THE SCIENCE OF STRONG RESTORED TEETH

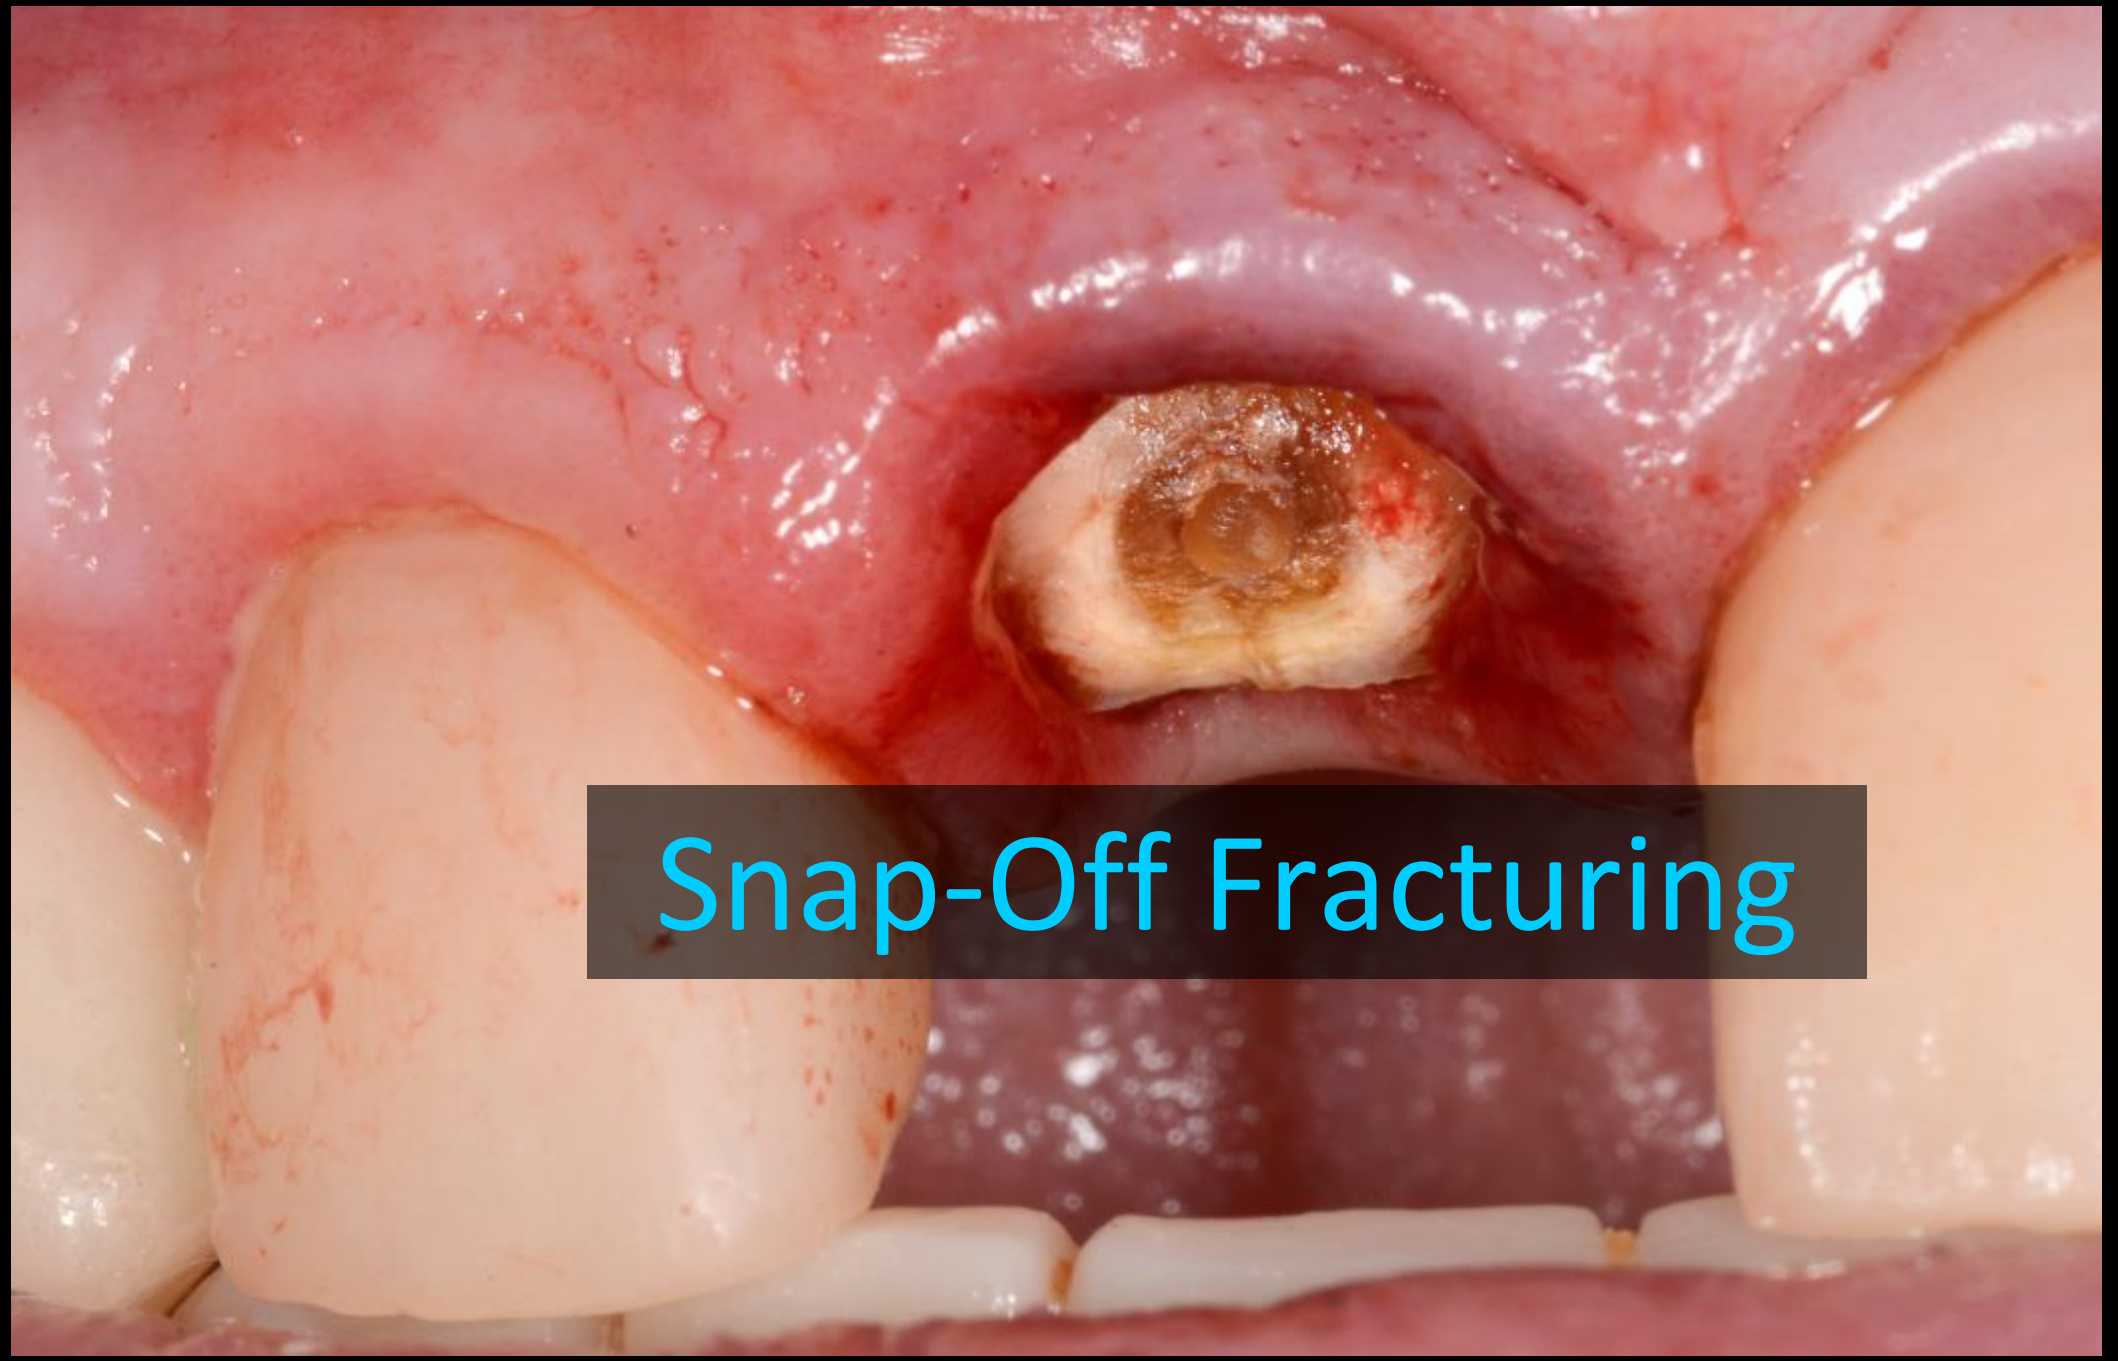
DR. DAVID CLARK

DR. ALEX FOK

Dr Alex Fok is a Mechanical Engineer with expertise in solid mechanics, structural analysis and mathematical modeling. He is currently the Academic Director of the Minnesota Dental Research Center for Biomaterials and Biomechanics (MDRCBB). The MDRCBB is an international leader in the development and application of novel characterization techniques for dental biomaterials, with long-standing collaboration with dental materials manufacturers. Dr Fok's research focuses on the development of techniques for material characterization, nondestructive examination, lifetime prediction and shape optimization of dental restorations. A principal aim of his research is to instill more engineering principles and analytical techniques into the design and assessment of dental restorations and treatments so as to improve their longevity and effectiveness.

In this case-based lecture today we explore:

- Coronal (vertical and cuspal) Fracturing
- Snap-Off Fracturing



Snap-Off Fracturing

Today's Summary

- Why things break…
- Modern cavity preparations
- Injection Overmolding as a 3rd option
- FEA of loading of teeth & composite
- Long term outcomes & case studies of composite overlays for cracked teeth
- When to endo, when to extract.

Modern Approach to Composite Restorations

Posterior Restoration

Black Triangle

Glossary

- Bending
  Mode of loading that creates curvature, resulting in tension on one side and compression on the other
- Compression
  Squeezing of an element
- Hooke's law
  This is obeyed when the strain of a material is proportional to the stress applied
- Shear
  Force or displacement that results in an angular change in shape of an element
- Spring
  Most fundamental structural element in solid mechanics
- Strain
  Displacement per unit length
- Strength
  Maximum stress required to cause fracture or debonding
- Stress
  Force per unit area
- Stress concentrator
  A structural feature that results in raised stresses within a small region
- Structural analysis or design triangle
  Material, geometry and load
- Tension
  Stretching of an element
- Toughness
  Energy required to create unit surface area
- Shape Optimization
- Modulus
- Brittle Materials vs. Ductile and Tough Materials
- Surface Resilience
- Cyclic Fatigue

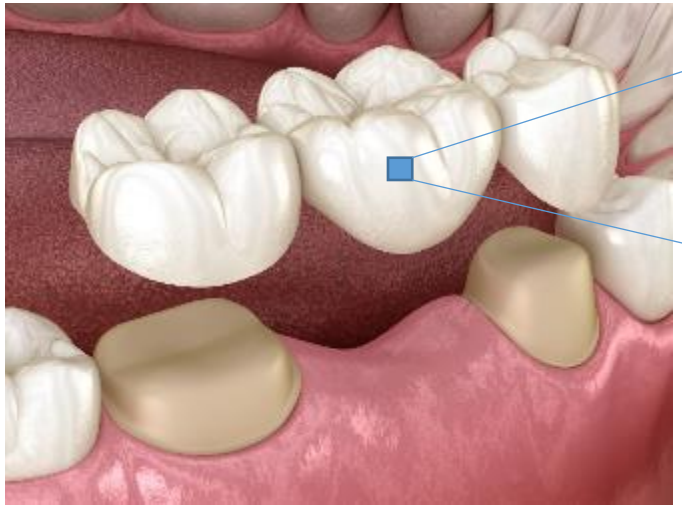
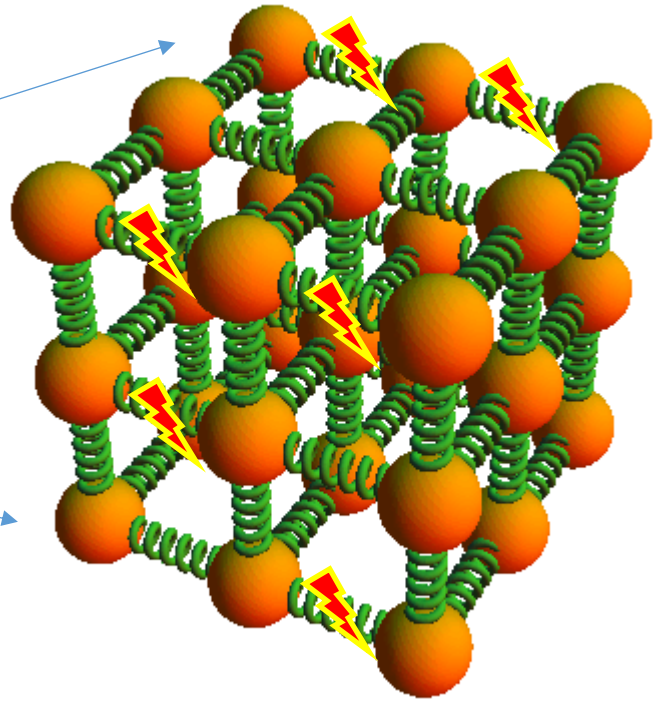
Basics of Solid Mechanics

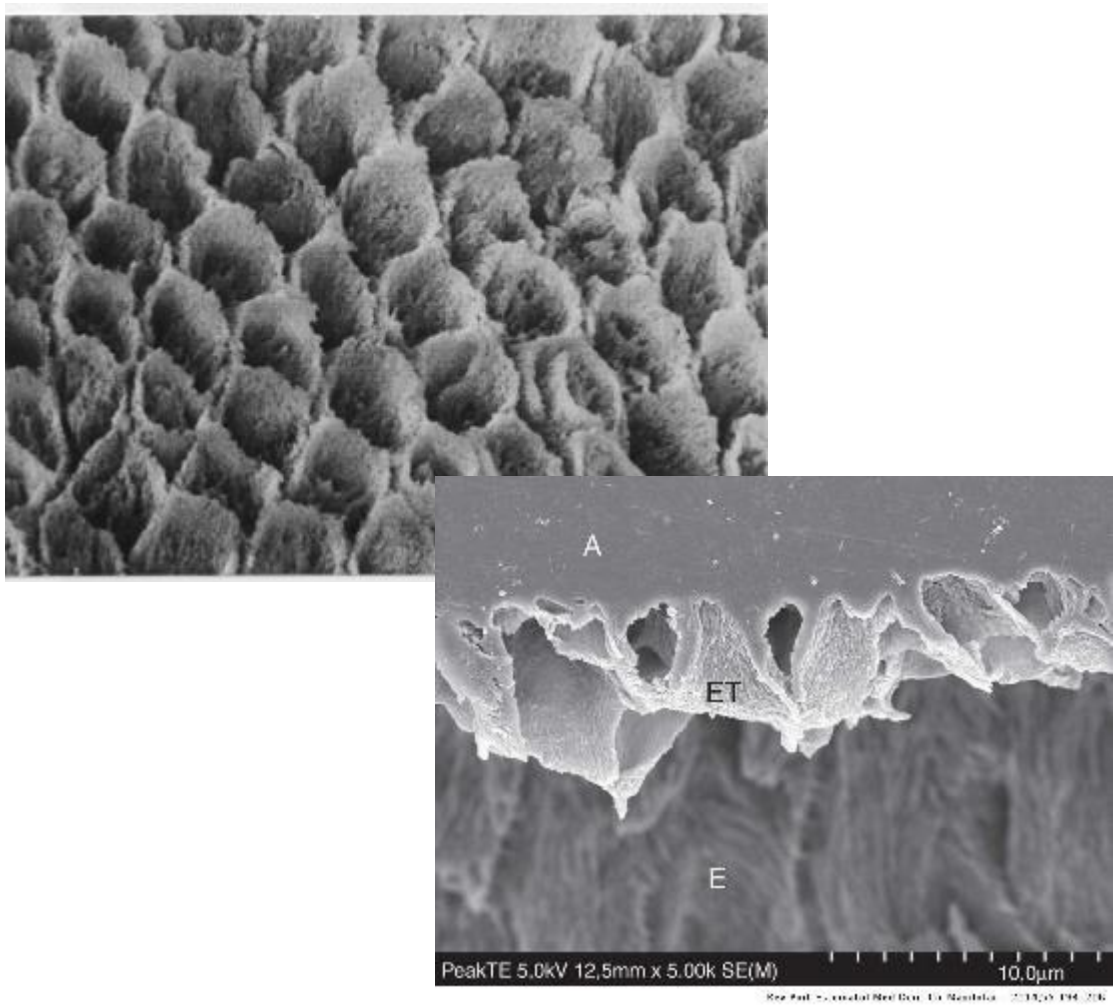


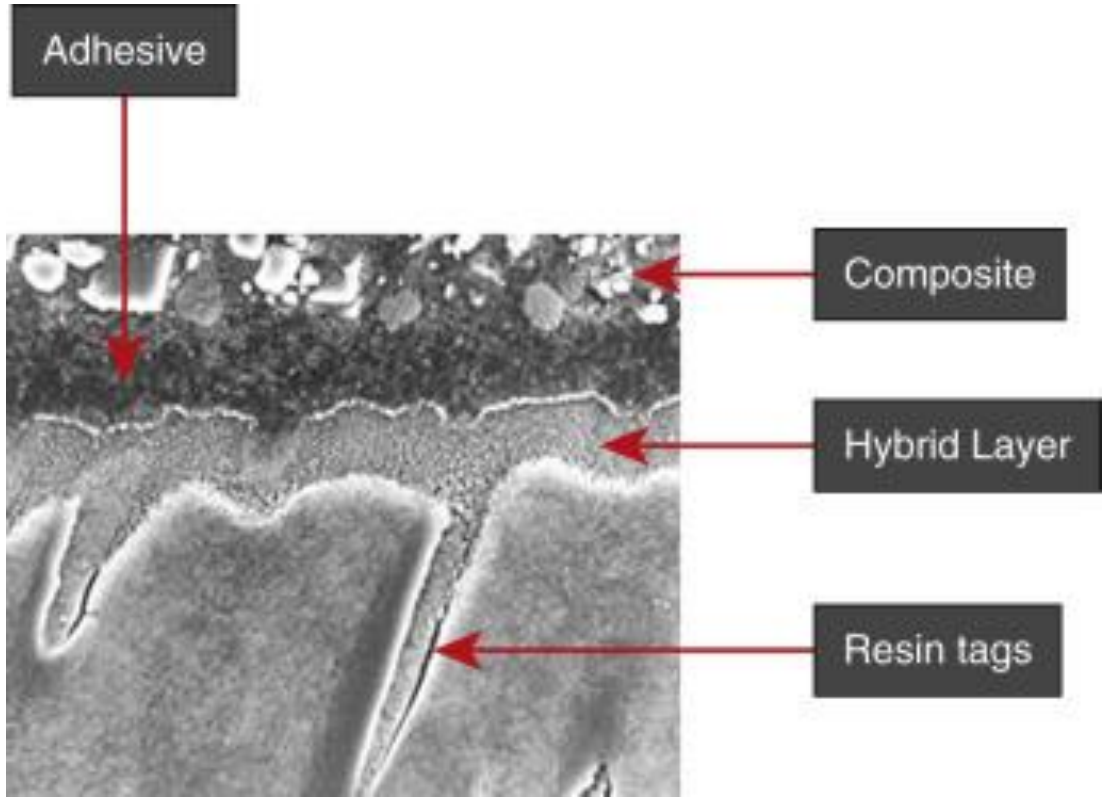
All solid structures can be considered as an assembly of many interconnected springs.



Enamel vs. Dentin Bonding

Bonding to enamel is mostly micromechanical.





Bonding to dentin is more complicated, involving a hybrid layer and exposed collagen that are prone to enzymatic attack.

Anisotropy : tooth tissues

Definitive Diagnosis of Early Enamel and Dentinal Cracks Based on Microscopic Evaluation

DAVID J. CLARK, DDS*
GERILYN G. SHEETS, DDS†
JACINTHE M. PAQUETTE, DDS‡

ABSTRACT

The diagnoses of cracked teeth and incomplete coronal fracture have historically been symptom based. The dental operating microscope at ×16 magnification can fundamentally change a clinician's ability to diagnose such conditions.

Clinicians have been observing cracks under extreme magnification for nearly a decade. Patterns have become clear that can lead to appropriate treatment prior to symptoms or destruction to tooth structure occur. Conversely, many cracks are not structural and can lead to misdiagnosis and overtreatment. Methodic microscopic examination, an understanding of crack progression, and an appreciation of the types of cracks will guide a doctor to making appropriate decisions.

Teeth can have structural cracks in various stages. To date, diagnosis and treatment are very often at end stage of crack development.

CLINICAL SIGNIFICANCE

This article gives new guidelines for recognition, visualization, classification, and treatment of cracked teeth based on the routine use of ×16 magnification. The significance of enamel cracks as they relate to dentinal cracks is detailed.

(*J Esthet Restor Dent* 15:XXX–XXX, 2003)

Microscopic and surgeon-driven diagnoses have been the accepted modalities for cracked teeth. The inherent limitations of the lack of visual confirmation result in diagnosis that often come too late in the treatment process. One lasting first impression of vision through a clinical microscope is the staggering array of cracks that exist within tooth structures. Traditional visualization (unaided or ocular assisted) limits the clinician's ability to assess the presence or severity of the majority of these cracks (Figure 1).

At extreme magnification levels (×14 and greater), the translucent nature of enamel yields a wealth of information. Subtle color changes within the enamel may indicate early decay, microleakage, and a lack of structural integrity of dentin and enamel. Being able to see previously invisible clues can lead restorative dentists to more appropriate early treatment of compromised teeth before devastating fractures, pulpal involvement, and periodontal breakdown occur. The value of early diagnosis of the structural breakdown of teeth will become even more significant with our aging population coupled with increased tooth retention in this population.

Nomenclature and Classification System for Enamel Cracks

Type I: Have little or no risk of underlying pathology

Type II: Have moderate risk of underlying pathology

Type III: Have high risk of underlying pathology

Type I: Have little or no risk of underlying pathology

A) Craze lines
B) Small vertical cracks
C) Cracks that follow natural anatomic grooves
D) Cracks with superficial stain penetration

Type II: Have moderate risk of underlying pathology

- E) V-shaped enamel ditching with or without an adjoining restoration often associated with a wear facet centered over an otherwise benign crack
- F) Cracks that detour from or do not follow natural anatomic grooves

Type III: Have high risk of underlying pathology

- G) Diagonal cracks branching off a vertical crack
- H) Horizontal or diagonal cracks that emanate from the corner of a restoration
- I) Cracks that house debris

Type III: Have high risk of underlying pathology

- J. Pair of cracks that outline an area (cusp or marginal ridge) of discolored enamel
- K. Crack with corresponding halo of brown, grey or white centered on crack
- **The tooth or the cusp is gray**

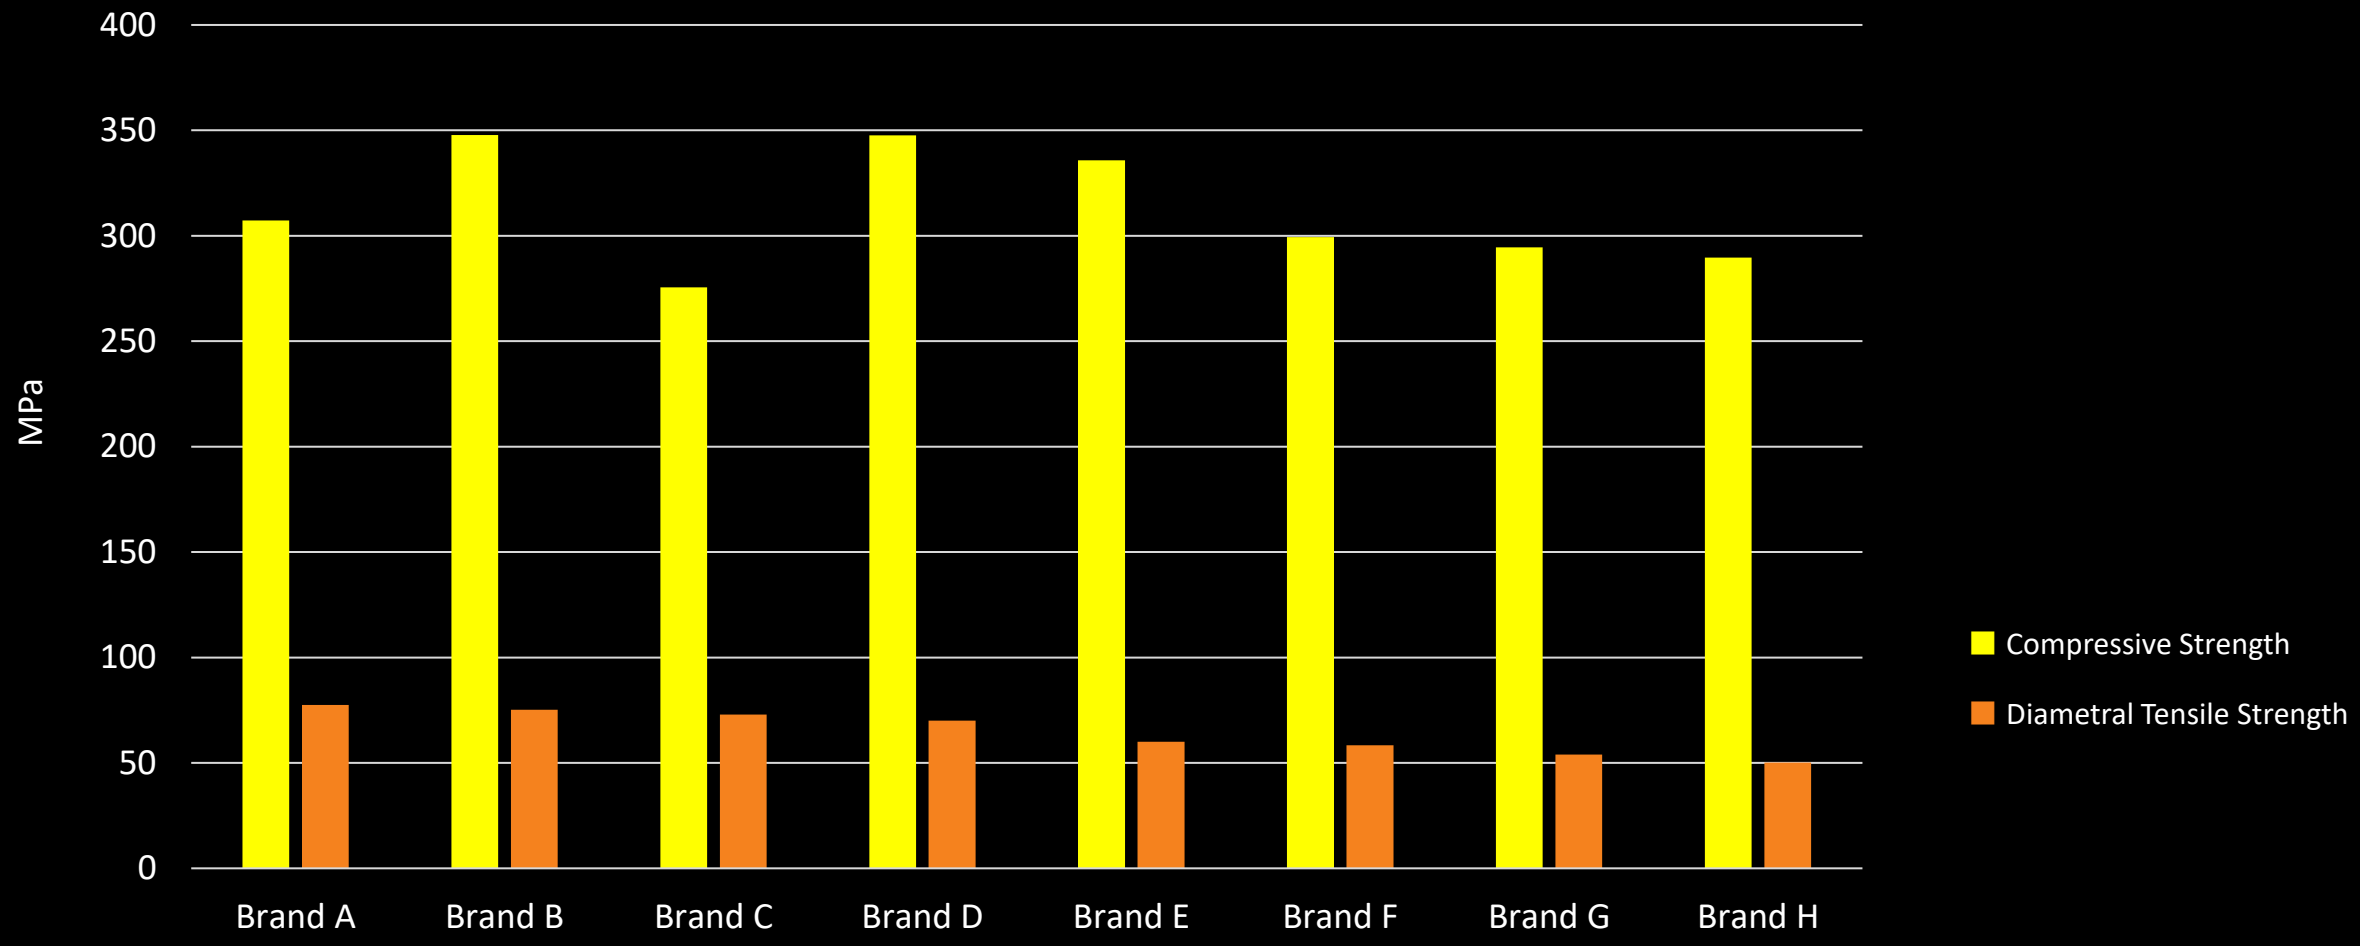
Epidemic of Cracked Teeth…Why?

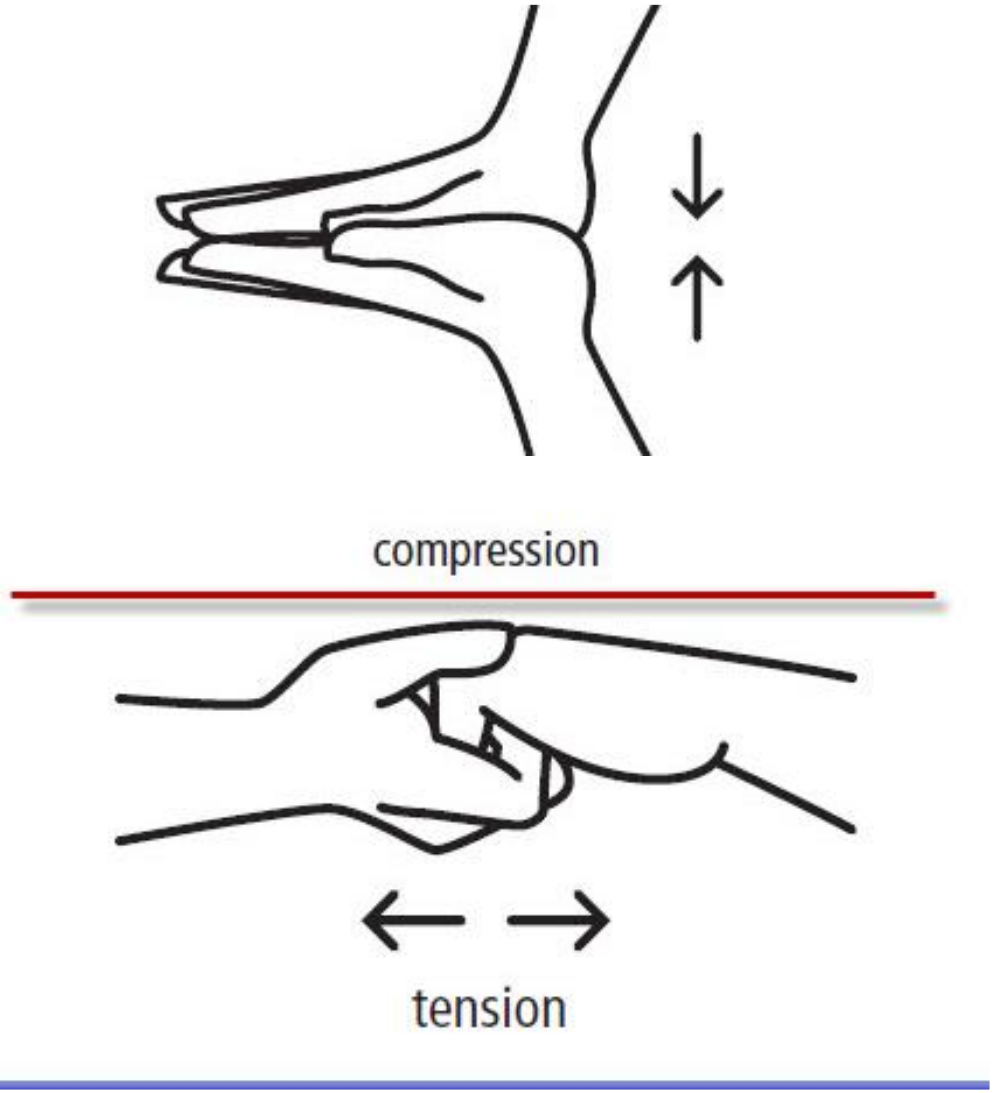
Brittle Materials with Tension joints

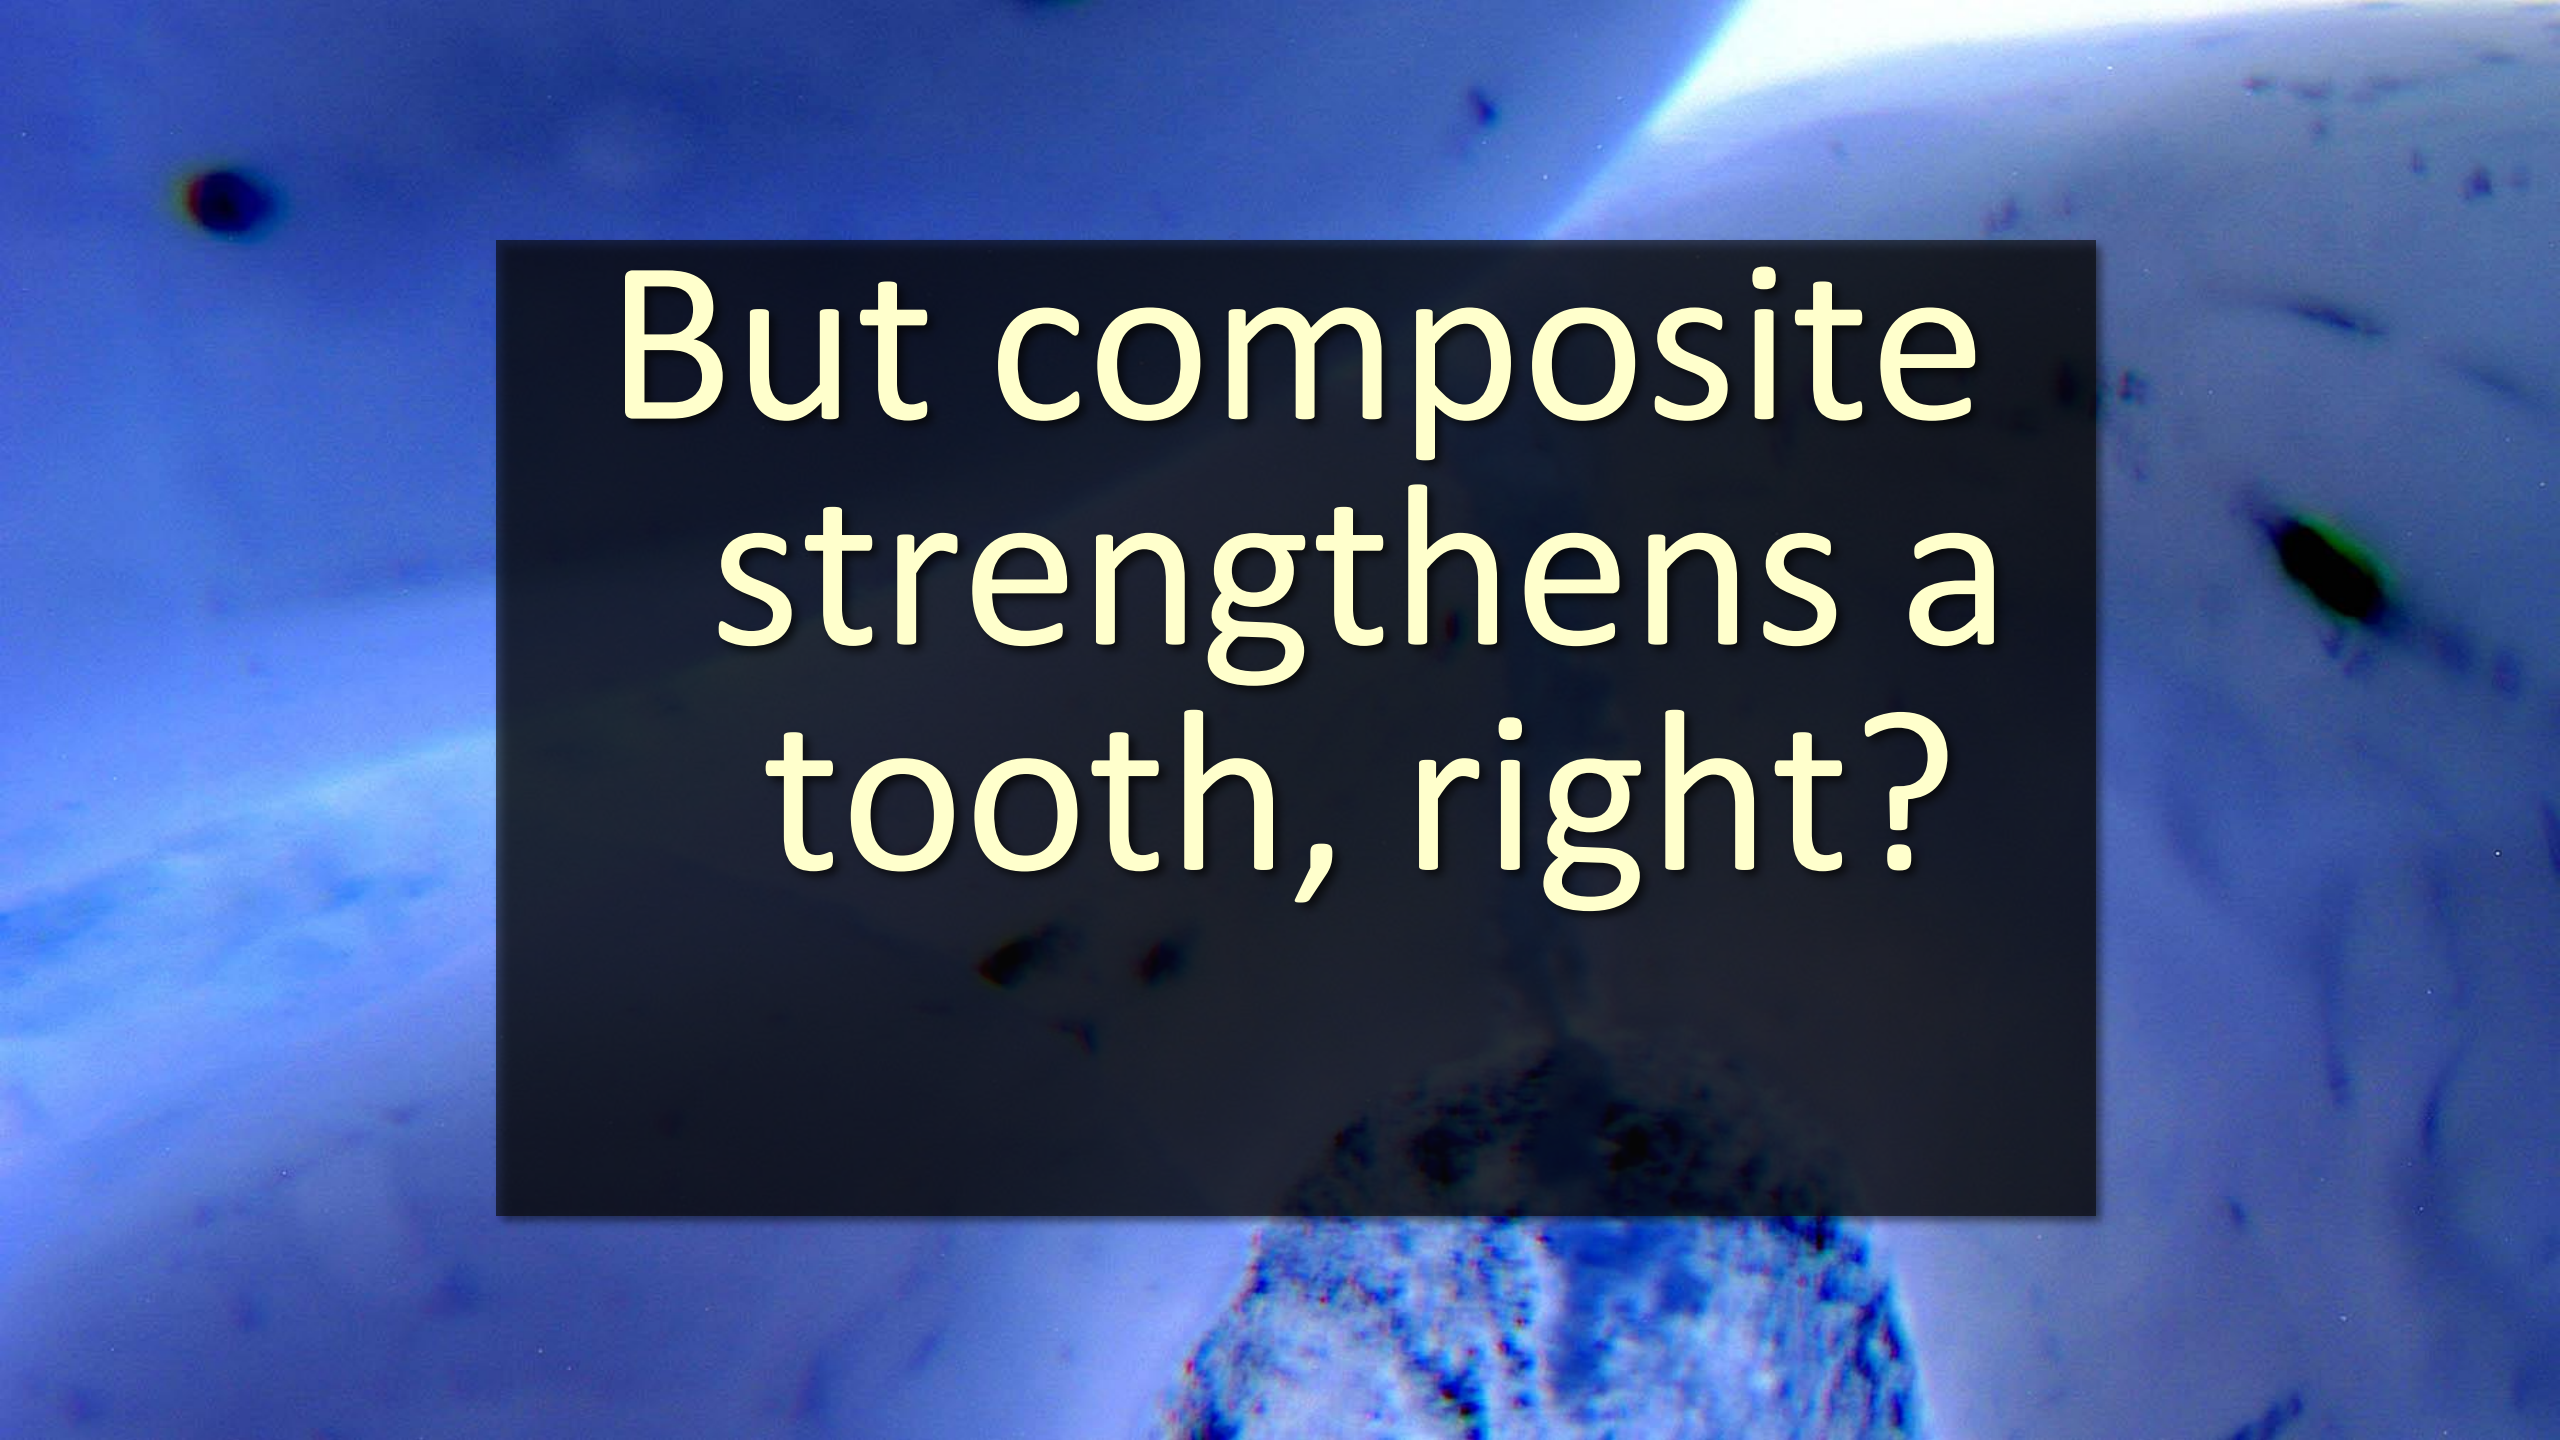
Composite Resin Material Properties

Compressive vs Diametral Tensile Strength



Compression vs. Tension is “Engineering 101”



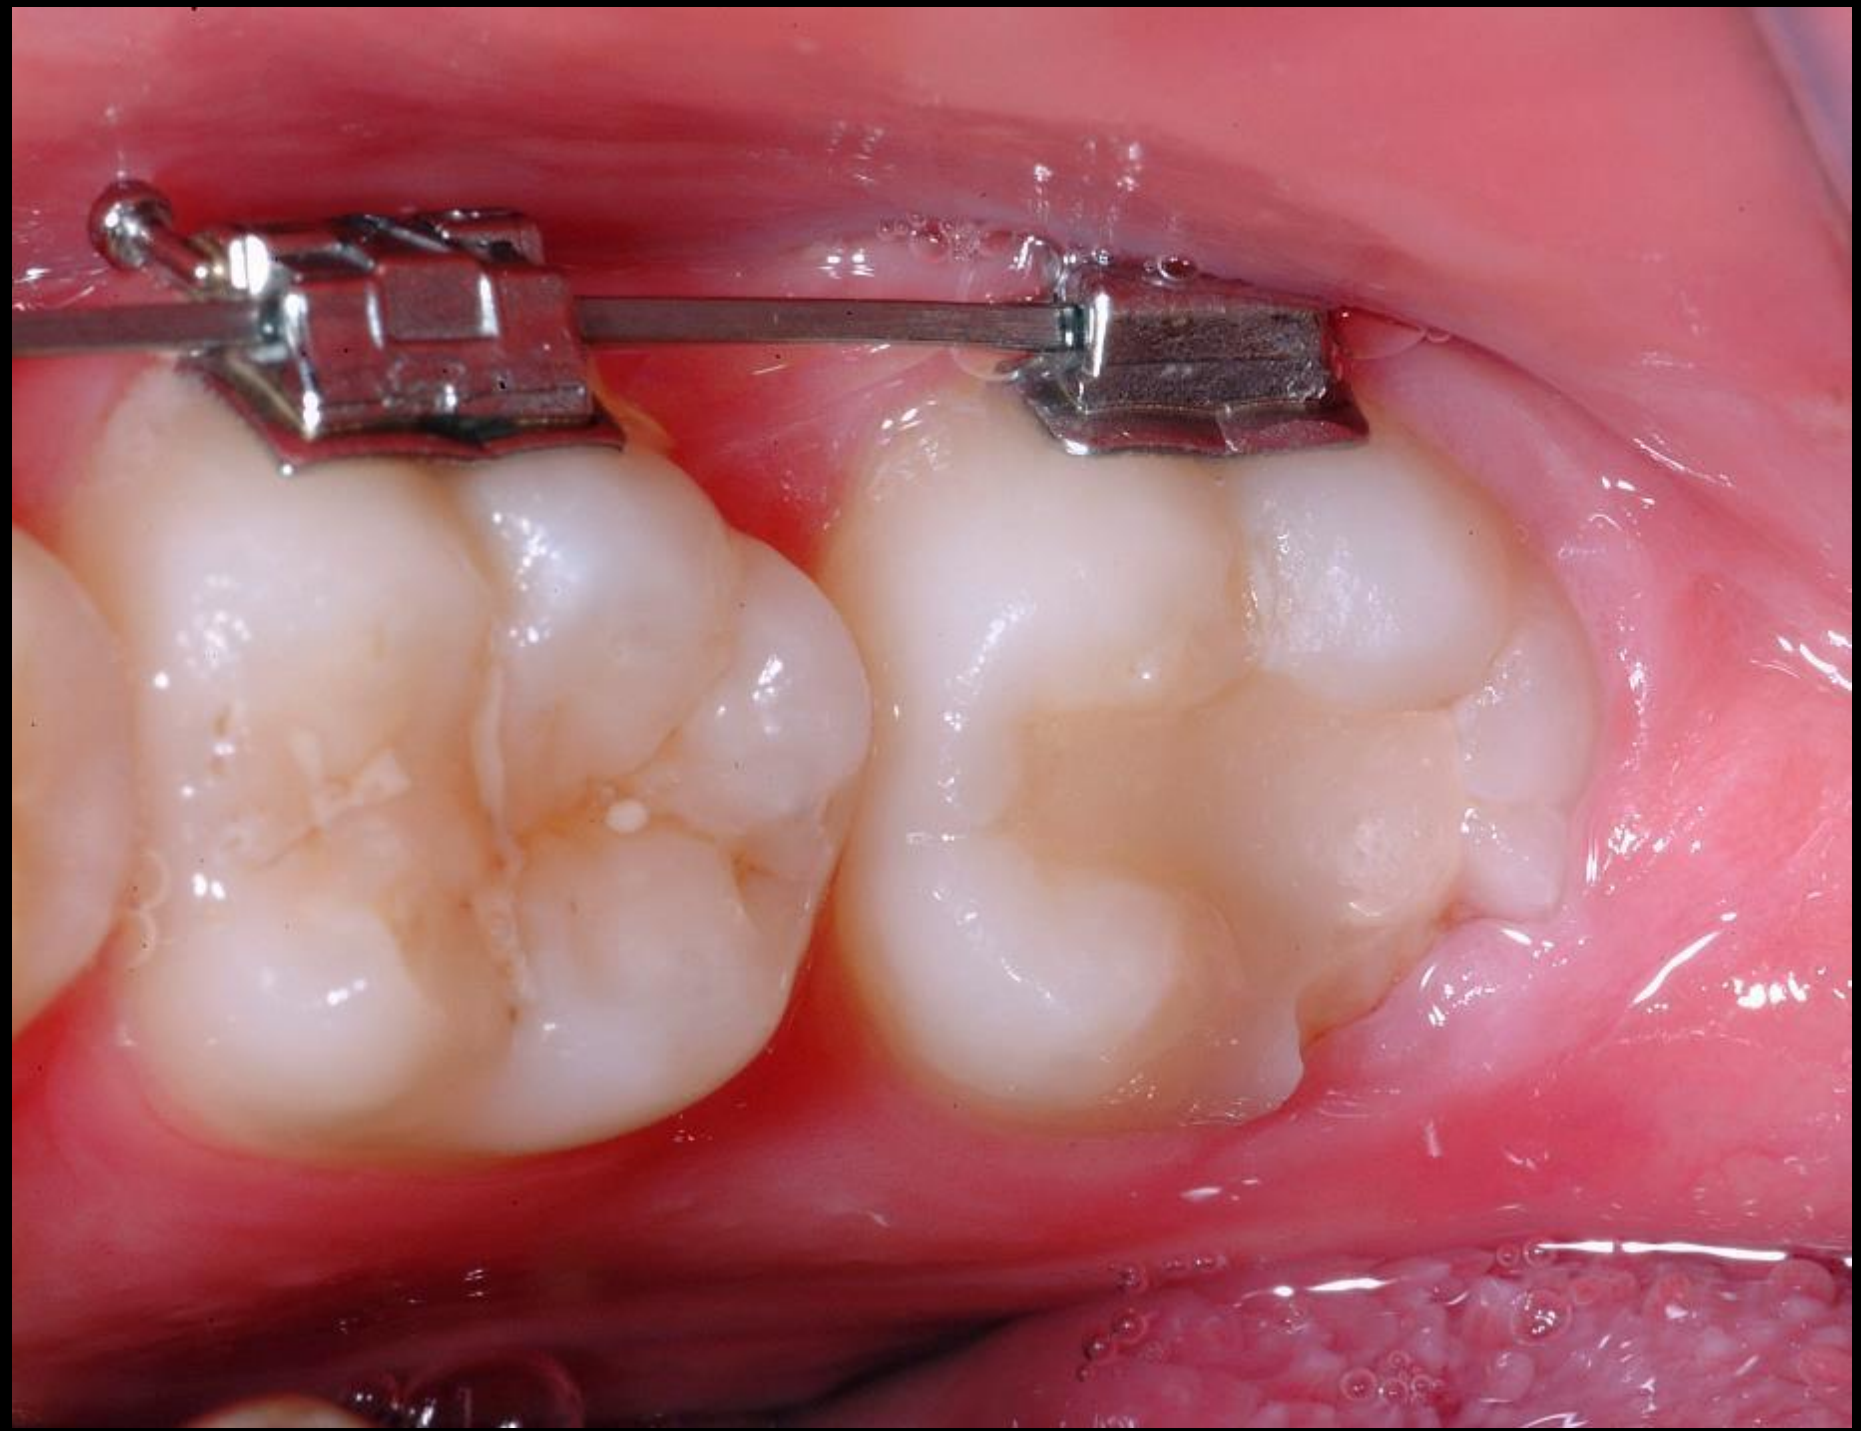


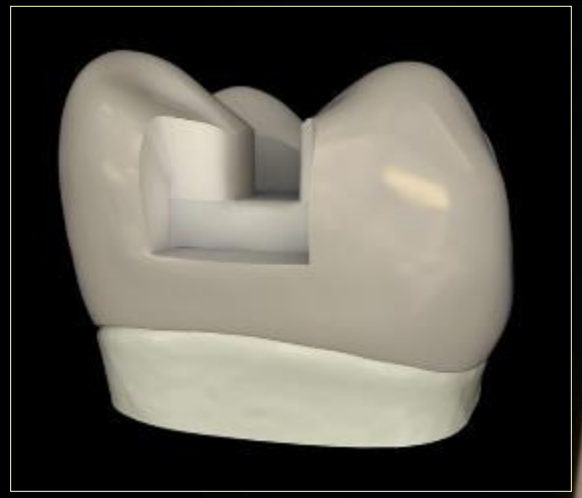
But composite strengthens a tooth, right?

Does composite strengthen the tooth?

No more than does amalgam

Wahl MJ, Schmitt MM, Overton DA, Gordon MK. Prevalence of cusp fractures in teeth restored with amalgam and with resin-based composite. JADA 135:1127-1132 (2004)

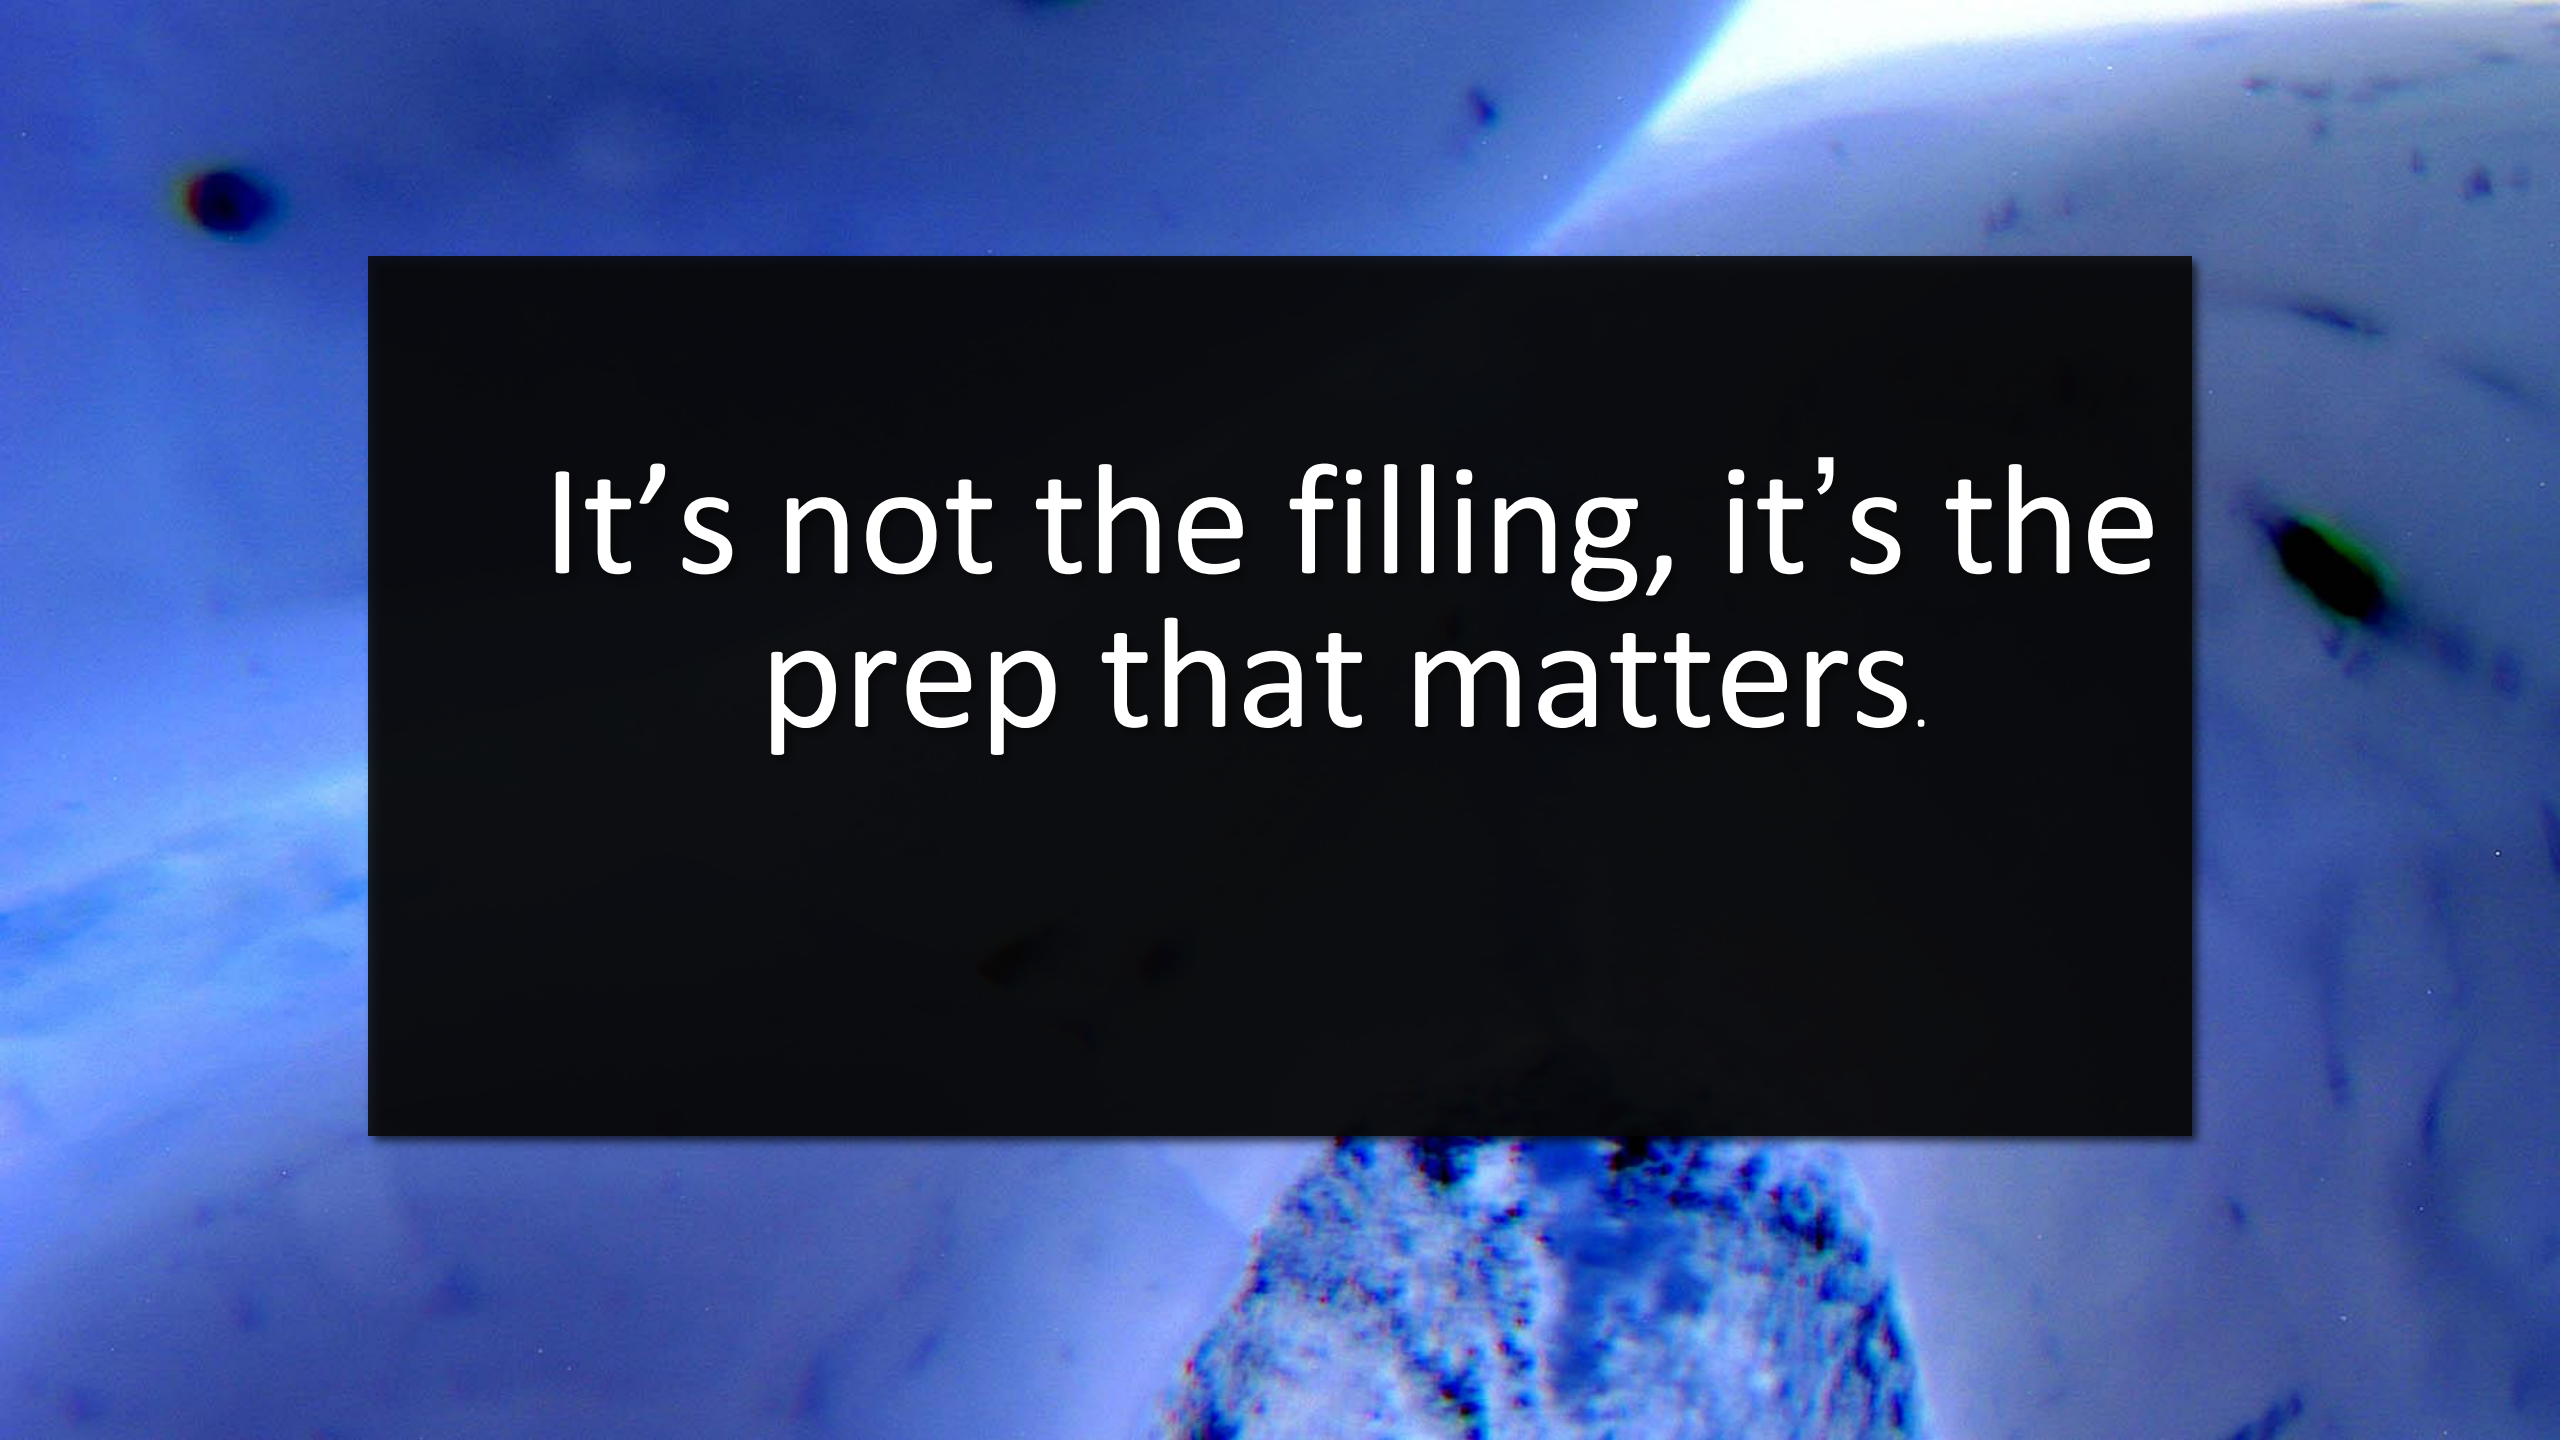




Boxes are bad.

Bevels make them less bad.

The Clark Class II replaces beveling with radius walls.



It’s not the filling, it’s the prep that matters.

RESTORATIVE

Fracture Resistant Endodontic and Restorative Preparations

Restoratively, It's Not the Size of the Hole, but the Shape of the Hole

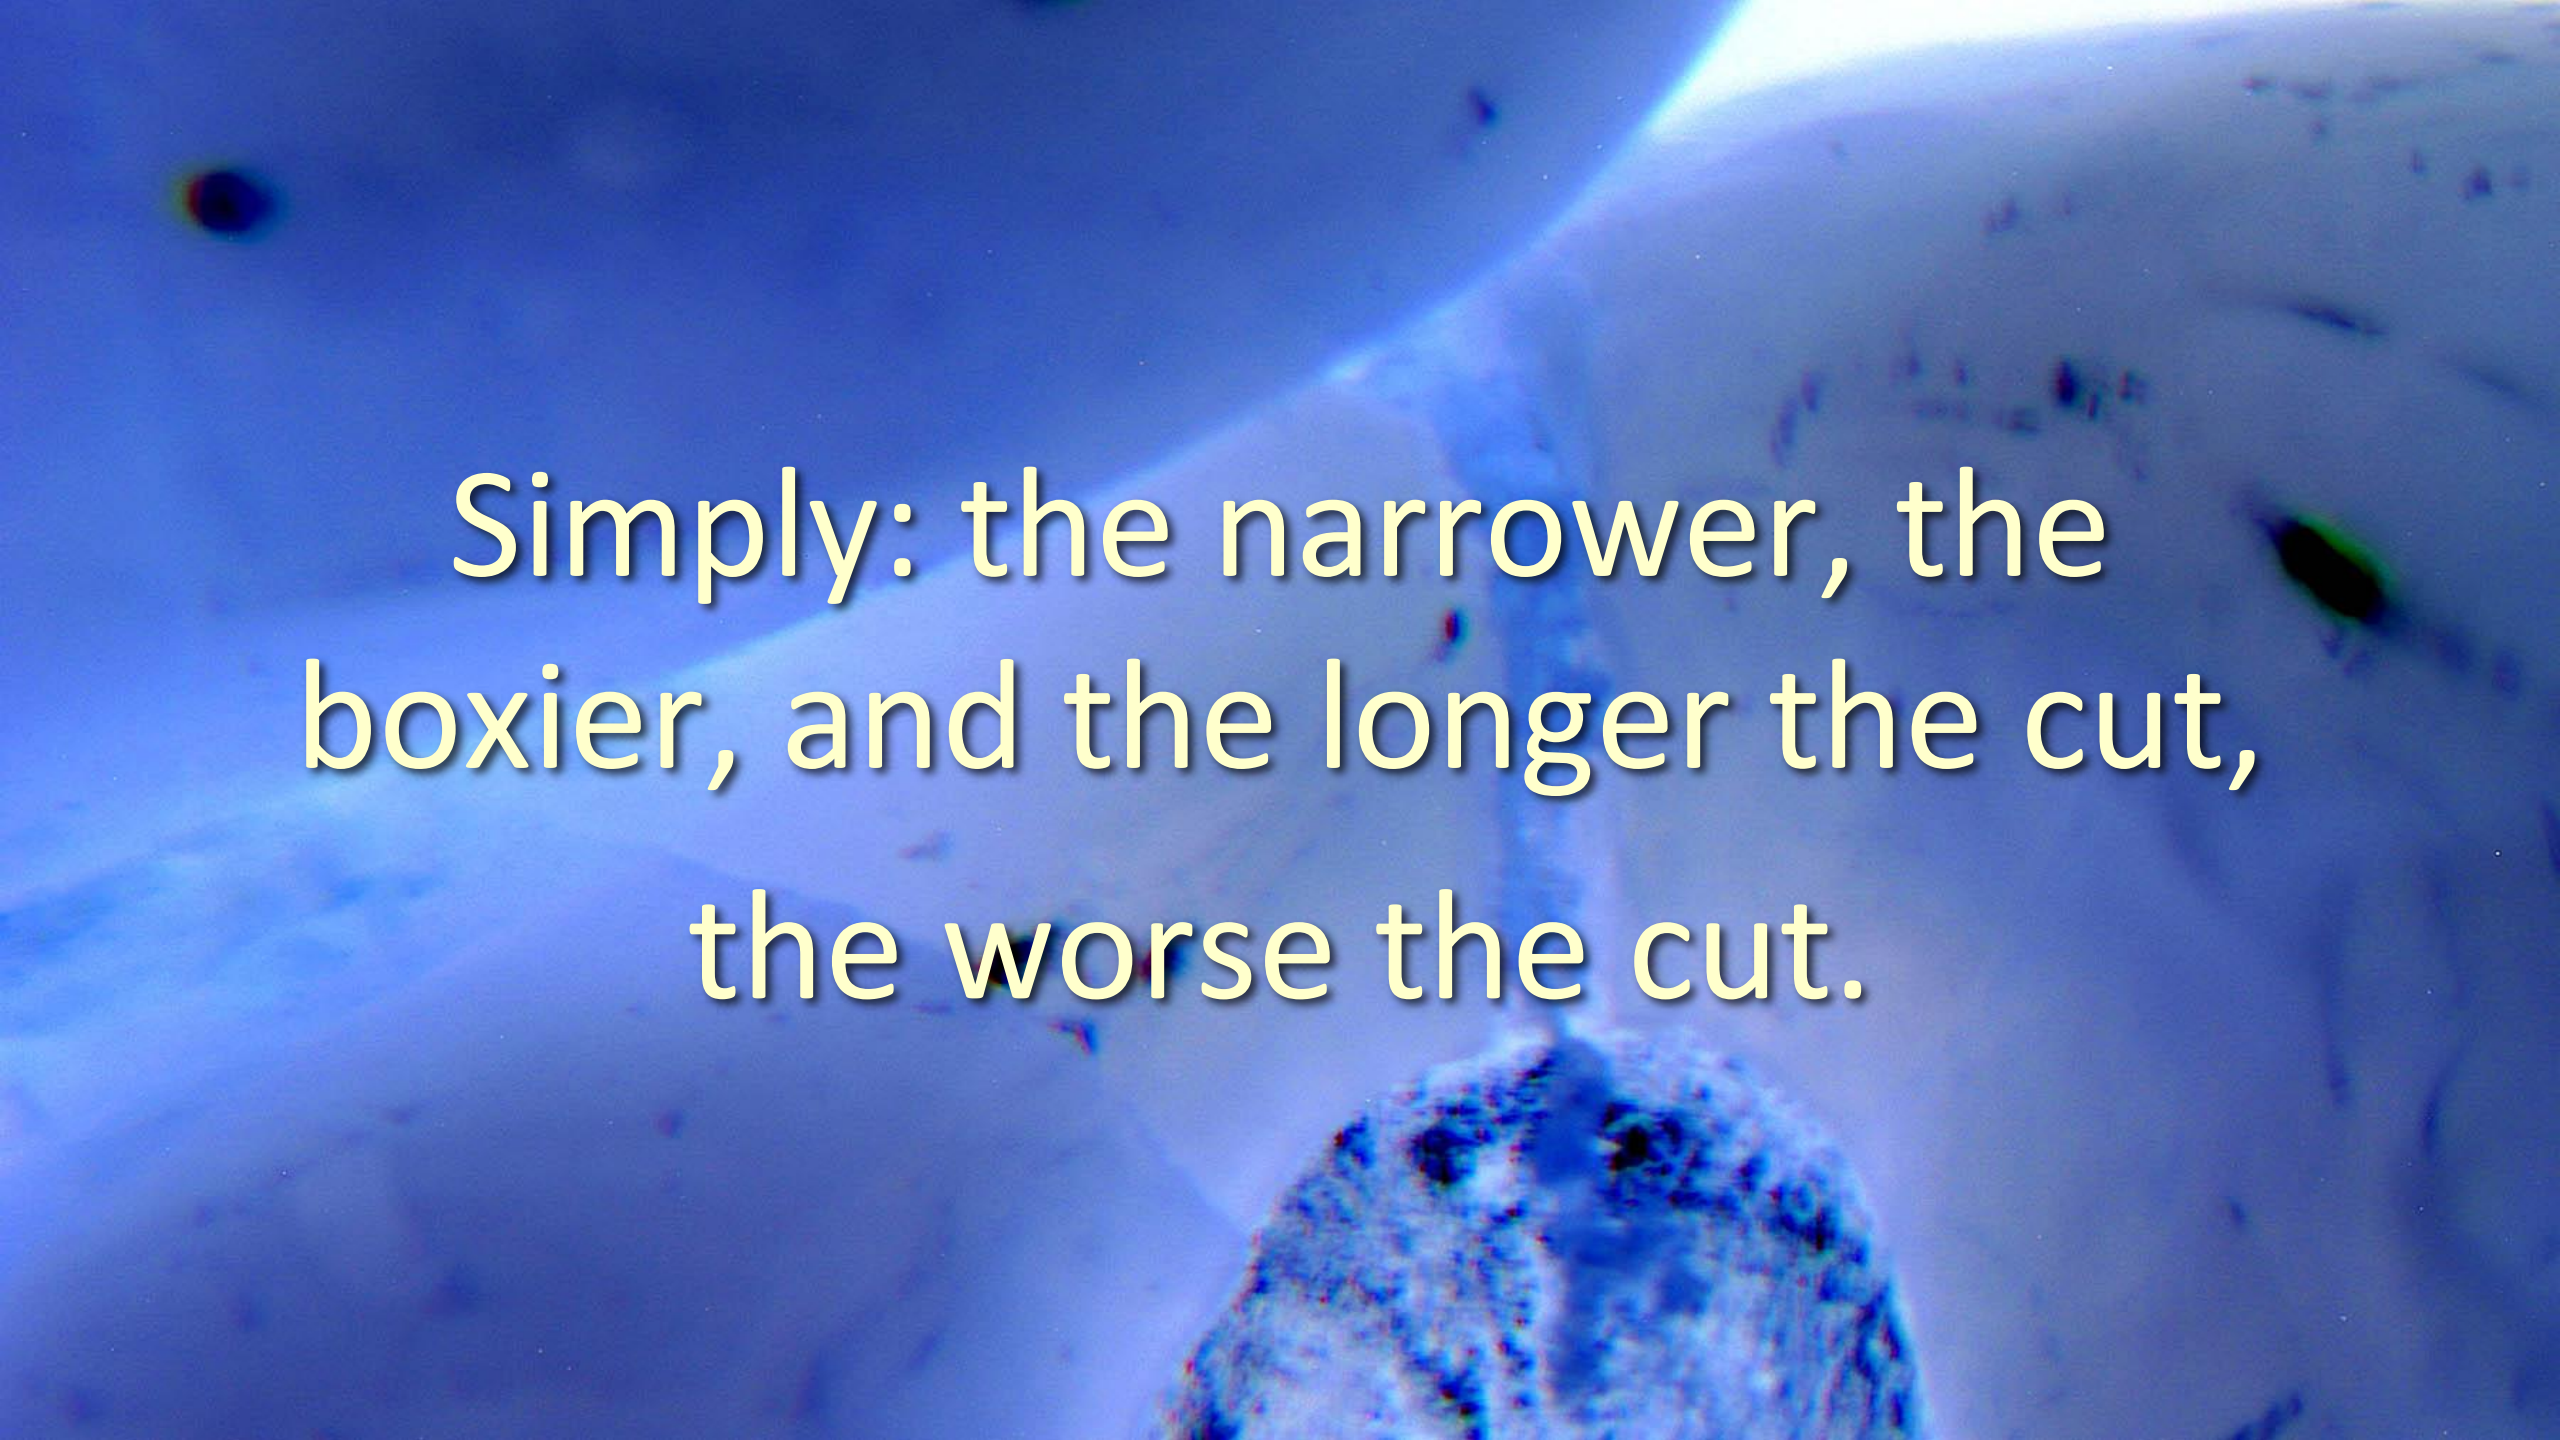
The formula for determining stress concentration due to a cavity preparation is $(1+2\sqrt{\frac{L}{R}})$ where L is length of the cut and R is the radius of the cut. In simple terms, the longer the cut, the worse the cut. A long narrow cut, interestingly, is worse than a wide, round-bottomed cut. One reason that intracoronal composites do not protect the tooth from long-term from

The formula for stress concentration in a cavity is

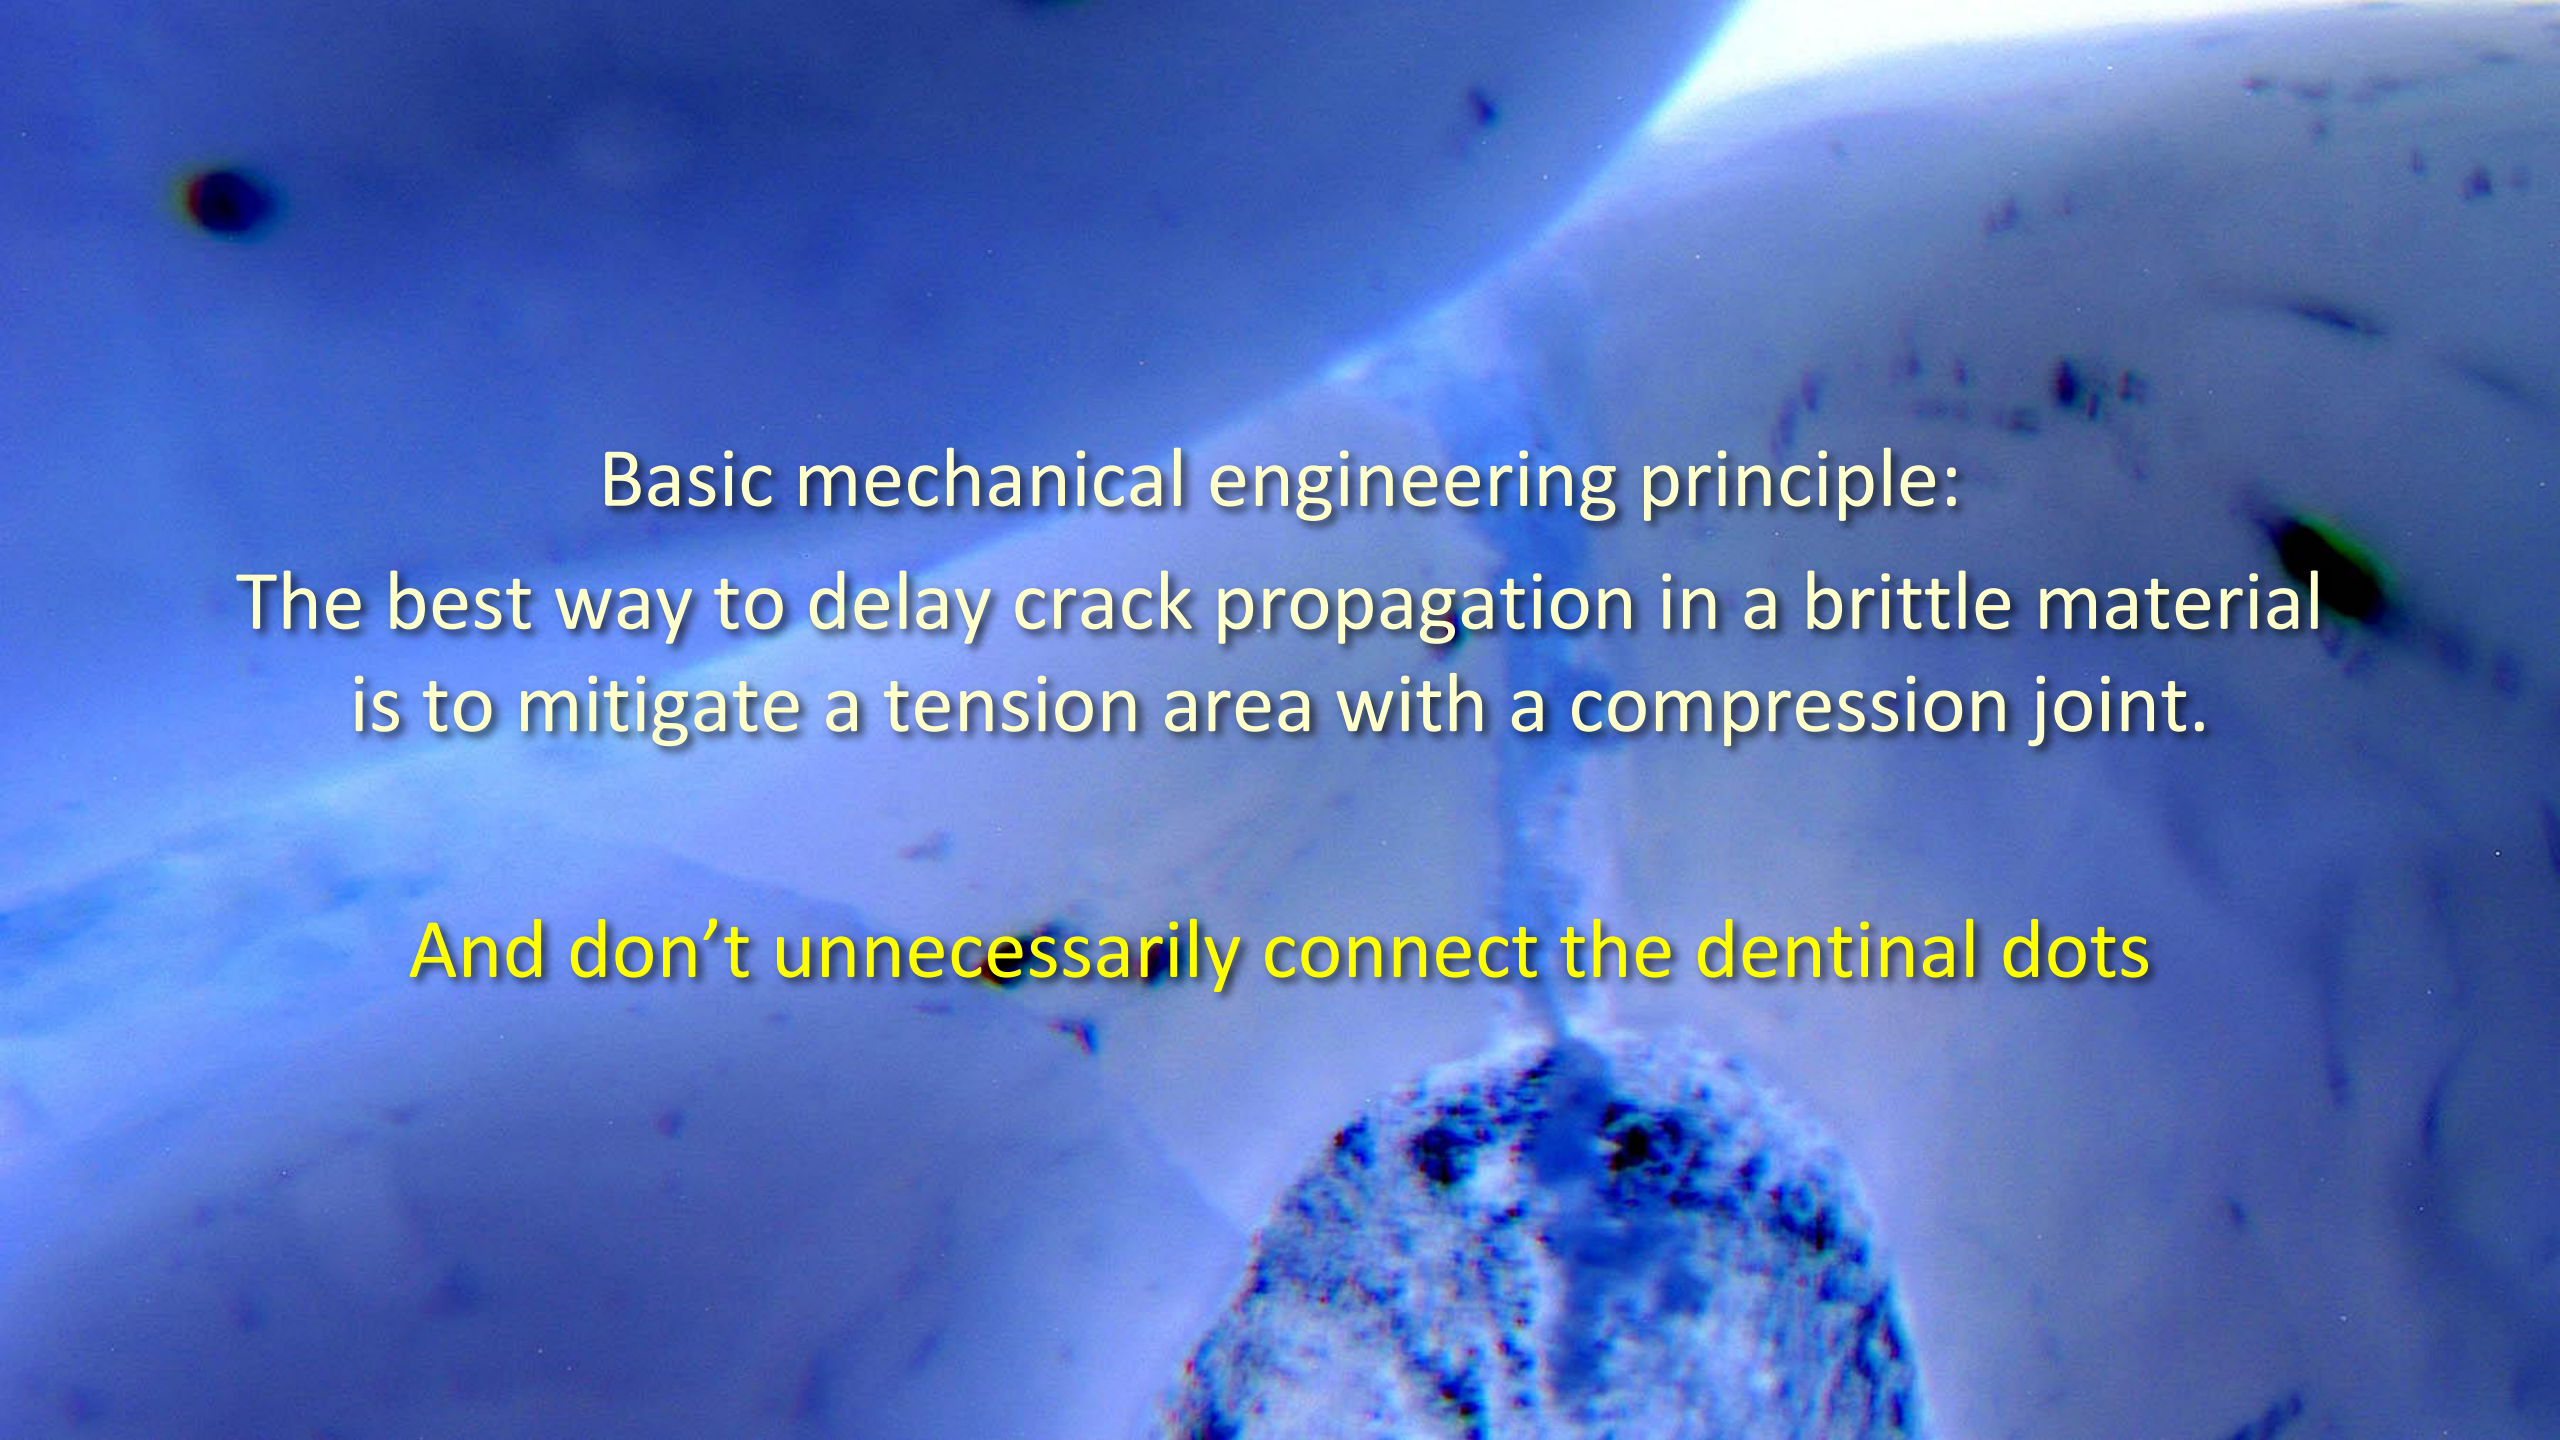
$$1 + 2\sqrt{L/R}$$

L is the depth of the cut.

R is the radius of the cut.



Simply: the narrower, the
boxier, and the longer the cut,
the worse the cut.



Basic mechanical engineering principle:
The best way to delay crack propagation in a brittle material is to mitigate a tension area with a compression joint.
And don’t unnecessarily connect the dentinal dots

The Prep?

A Six Year Evaluation of Cracked Teeth Diagnosed with Reversible Pulpitis: Treatment and Prognosis

Keith V. Krell, DDS, MS, MA, and Eric M. Rivera, DDS, MS†*

Abstract

The purpose of this investigation was to report on the clinical outcomes of cracked teeth diagnosed with reversible pulpitis (RP). Eight thousand one hundred seventy-five patients referred for evaluation and treatment during a 6-year period had medical and dental histories, radiographs, pulpal and periapical diagnosis, periodontal probings, direct identification of crack(s) with transillumination, and biting responses on various cusps recorded. All data were stored daily in a database. All cases were treatment planned according to the pulpal and periapical diagnosis. Cases with RP were treatment planned for crowns only, regardless of periapical diagnosis. All patients were recalled at 1 year unless root canal treatment was needed before the anniversary. Results indicated that cracks were identified in 9.7% (796 of 8175) of all teeth evaluated during this time period. Of 127 patients specifically diagnosed with RP, 27 converted to irreversible pulpitis (N = 21) in 58 days or to necrotic pulp (N = 6) in 149 days. To date, none of the original remaining 100 cases of RP have required root canal treatment. The outcomes of this study suggest that if a marginal ridge crack is identified early enough in teeth with a diagnosis of RP and a crown is placed, root canal treatment will be necessary in about 20% of these cases within a 6-month period. *(J Endod 2007;33:1405–1407)*

Key Words

Cracked teeth, reversible pulpitis

doi:10.1016/j.joen.2007.08.015

The Fall/Winter 1997 AAE Colleagues for Excellence article entitled "Cracking the Cracked Tooth Code" (http://www.aae.org/NR/rdonlyres/7D73B05C-FEE4-4B00-AB37-0860056F163BC/0/fw97ccfe.pdf) defined 5 types of tooth cracks. Four of the 5 cracks are associated with coronal defects generated from chewing and biting events (1). Teeth with craze lines have no pain, show lines in the enamel, but no "shadows" in the dentin with transillumination. Teeth with fractured cusps have mild pain to biting on a specific cusp, usually a marginal ridge and buccal or lingual groove crack in the dentin, seen as a shadow with transillumination and a Class II restoration. Removal of the restoration might result in the cusp breaking off. Cracked teeth might or might not have a restoration, will exhibit acute pain on mastication, early brief pain to cold, centrally located mesial-to distal marginal ridge crack(s) seen in the dentin as a shadow(s) with transillumination, normal-to-deep periodontal probings associated with the crack, no detectable movement of cusps with an explorer, and might require removal of existing restorations to definitively diagnose. The pulpal and periapical diagnoses are dependent on the extent of the crack and duration of the symptoms. Split teeth usually have marked pain to chewing, can be considered an extension of the cracked tooth, have mesiodistal cracks extending across both marginal ridges with detectable buccal and lingual cusp separation with an explorer, and deep probings with both marginal ridges. Vertical root fractures begin in the roots of teeth that usually have had endodontic treatment, extend in the buccal-to-lingual plane, usually have minimal signs or symptoms, might have normal probings, and require surgical assessment to complete the diagnosis.

The treatment of teeth diagnosed as a cracked tooth has largely been variable and empirical. The Fall/Winter 1997 AAE Colleagues for Excellence article entitled "Cracking the Cracked Tooth Code" suggested "the treatment plan will vary depending on the location and extent of the crack" and noted that "any thermal sensitivity probably indicates the crack extends near or into the pulp, and root canal treatment will be necessary prior to restoring the tooth with a crown" (1). The juxtaposition to assuming the tooth will need root canal treatment before the crown is to place the crown first, see whether symptoms subside, and only perform root canal treatment when the pulpal and periradicular status dictates treatment. Ailor (2) presented a "flow chart" that took into consideration the pulp status at the time of discovery of the crack. He suggested temporizing the tooth with a temporary crown and monitoring it for symptoms.

Incidence data from Hiatt (3) and Cameron (4) found that the most frequently involved teeth were mandibular molars followed by maxillary premolars and then by maxillary first molars. Weine et al (5) found that the most frequently involved teeth were mandibular molars followed by maxillary molars and then by maxillary premolars.

To date there have been no studies that have looked at teeth diagnosed with cracks (cracked teeth) that have a pulpal diagnosis of reversible pulpitis (RP) and are subsequently crowned without initial root canal treatment. The purpose of this investigation was to report on the clinical outcomes of cracked teeth that were initially diagnosed with RP that were crowned during a 6-year period. Specific questions to be answered were the following: (1) what are the locations of these cracked teeth in the mouth? (2) What is the periodontal status of these cracked teeth? (3) Where are the cracks located on the teeth? (4) How many teeth required root canal therapy? (5) What clinical changes occurred in or around the teeth requiring root canal therapy?

A Six Year Evaluation of Cracked Teeth Diagnosed with Reversible Pulpitis: Treatment and Prognosis

Keith V. Krell, DDS, MS, MA, and Eric M. Rivera, DDS, MS†*

Abstract

The purpose of this investigation was to report on the clinical outcomes of cracked teeth diagnosed with reversible pulpitis (RP). Eight thousand one hundred seventy-five patients referred for evaluation and treatment during a 6-year period had medical and dental histories, radiographs, pulpal and periapical diagnosis, periodontal probings, direct identification of crack(s) with transillumination, and biting responses on various cusps recorded. All data were stored daily in a database. All cases were treatment planned according to the pulpal and periapical diagnosis. Cases with RP were treatment planned for crowns only, regardless of periapical diagnosis. All patients were recalled at 1 year unless root canal treatment was needed before the anniversary. Results indicated that cracks were identified in 9.7% (796 of 8175) of all teeth evaluated during this time period. Of 127 patients specifically diagnosed with RP, 27 converted to irreversible pulpitis (N = 21) in 58 days or to necrotic pulp (N = 6) in 149 days. To date, none of the original remaining 100 cases of RP have required root canal treatment. The outcomes of this study suggest that if a marginal ridge crack is identified early enough in teeth with a diagnosis of RP and a crown is placed, root canal treatment will be necessary in about 20% of these cases within a 6-month period. *(J Endod 2007;33:1405–1407)*

The Fall/Winter 1997 AAE Colleagues for Excellence article entitled "Cracking the Cracked Tooth Code" (http://www.aae.org/NR/rdonlyres/7D73B05C-FEE4-4B00-AB37-086056F163BC/0/fw97ccfe.pdf) defined 5 types of tooth cracks. Four of the 5 cracks are associated with coronal defects generated from chewing and biting events (1). Teeth with craze lines have no pain, show lines in the enamel, but no "shadows" in the dentin with transillumination. Teeth with fractured cusps have mild pain to biting on a specific cusp, usually a marginal ridge and buccal or lingual groove crack in the dentin, seen as a shadow with transillumination and a Class II restoration. Removal of the restoration might result in the cusp breaking off. Cracked teeth might or might not have a restoration, will exhibit acute pain on mastication, early brief pain to cold, centrally located mesial-to distal marginal ridge crack(s) seen in the dentin as a shadow(s) with transillumination, normal-to-deep periodontal probings associated with the crack, no detectable movement of cusps with an explorer, and might require removal of existing restorations to definitively diagnose. The pulpal and periapical diagnoses are dependent on the extent of the crack and duration of the symptoms. Split teeth usually have marked pain to chewing, can be considered an extension of the cracked tooth, have mesiodistal cracks extending across both marginal ridges with detectable buccal and lingual cusp separation with an explorer, and deep probings with both marginal ridges. Vertical root fractures begin in the roots of teeth that usually have had endodontic treatment, extend in the buccal-to-lingual plane, usually have minimal signs or symptoms, might have normal probings, and require surgical assessment to complete the diagnosis.

The treatment of teeth diagnosed as a cracked tooth has largely been variable and empirical. The Fall/Winter 1997 AAE Colleagues for Excellence article entitled "Cracking the Cracked Tooth Code" suggested "the treatment plan will vary depending on the location and extent of the crack" and noted that "any thermal sensitivity probably indicates the crack extends near or into the pulp, and root canal treatment will be necessary prior to restoring the tooth with a crown" (1). The juxtaposition to assuming the tooth will need root canal treatment before the crown is to place the crown first, see whether symptoms subside, and only perform root canal treatment when the pulpal and periradicular status dictates treatment. Ailor (2) presented a "flow chart" that took into consideration the pulp status at the time of discovery of the crack. He suggested temporizing the tooth with a temporary crown and monitoring it for symptoms.

Incidence data from Hiatt (3) and Cameron (4) found that the most frequently involved teeth were mandibular molars followed by maxillary premolars and then by maxillary first molars. Weine et al (5) found that the most frequently involved teeth were mandibular molars followed by maxillary molars and then by maxillary premolars.

To date there have been no studies that have looked at teeth diagnosed with cracks (cracked teeth) that have a pulpal diagnosis of reversible pulpitis (RP) and are subsequently crowned without initial root canal treatment. The purpose of this investigation was to report on the clinical outcomes of cracked teeth that were initially diagnosed with RP that were crowned during a 6-year period. Specific questions to be answered were the following: (1) what are the locations of these cracked teeth in the mouth? (2) What is the periodontal status of these cracked teeth? (3) Where are the cracks located on the teeth? (4) How many teeth required root canal therapy? (5) What clinical changes occurred in or around the teeth requiring root canal therapy?

6 year evaluation ….the first study of its kind

A Six Year Evaluation of Cracked Teeth Diagnosed with Reversible Pulpitis: Treatment and Prognosis

%	8.50	8.89	6.10	4.55	17.61	11.00	2.63	0.45	9.74

Materials and Methods

There were 8175 patients included in this study from a private endodontic practice population during a 6-year period. The patients were recorded consecutively as they were referred to the endodontist for evaluation and appropriate treatment during the 6-year period. Besides the standard medical history and subjective history, the endodontist was responsible for the diagnosis of all teeth and recorded the following information for all teeth:

(1) Pulpal response to cold or hot.
(2) Periapical response to pressure, palpation, and percussion.
(3) Buccal and lingual periodontal probings were recorded in the mesial and distal interproximal spaces and furca. These interproximal probings would be directed precisely where marginal ridge cracks were identified to indicate the deepest probing of the crack. A total of 6 probing points were recorded for each tooth.
(4) Identification of a crack(s) with direct transillumination and visualization with and without magnification. The identified crack had to block light transmission and show a definite shadow with both the buccal and lingual coronal light placement. Teeth not exhibiting a shadow were considered to have "crazings" and were not included in this study.
(5) Responses to biting on various cusps of the diagnosed tooth, with at least 1 cusp exhibiting pain to biting on either a burlew wheel or Tooth Slooth (Professional Results, Inc, Laguna [illegible]).

Teeth were diagnosed with RP if (1) there was no history of spontaneous pain; (2) the response to cold went away in less than 3–5 seconds; (3) there was no radiographic pathosis.

No teeth were included in this part of the study that could not be confirmed by visualization as having an identifiable crack even if biting sensitivity was present. Restorations were removed only for patients with pulpal diagnoses that required root canal treatment. Teeth diagnosed as cusp fractures, split teeth, and vertical root fractures were also excluded from this study (6). All patients were recalled at 1 year unless root canal treatment was needed before the anniversary; then recall was 1 year later after treatment. The recall therefore extended into a seventh year of the data collection.

All cases were treatment planned according to the pulpal and periapical diagnosis. Cases with RP were treatment planned for crowns only, regardless of periapical diagnosis.

Results

Of the 8175 cases seen during the 6-year period, 796 cases were diagnosed as cracked teeth (9.7%). Mandibular second molars (243/796, 30%) had the largest incidence followed by mandibular first molars (231/796, 29%) and maxillary first molars (167/796, 21%). All teeth are included in Table 1.

Cases with RP had the following distribution: mandibular first molars (41/127, 32%), maxillary first molars (33/127, 25%), and mandibular second molars (29/127, 23%). All teeth are included in Table 2.

Of 127 patients specifically diagnosed with RP, 27 converted to irreversible pulpitis (N = 21) in 58 days or to necrotic pulp (N = 6) in 149 days. The distribution of teeth requiring root canal therapy was as follows: maxillary first molars (9/27, 33%), mandibular second molars (8/27, 29%), mandibular first molars (7/27, 26%), and maxillary second molars (3/27, 11%).

All teeth had initial interproximal probings less than 3 mm in the space associated with the identified crack. Increased interproximal probings were associated with the fractured marginal ridge for only 5 of the 27 teeth requiring root canal treatment. The greatest increase in probing depth was 2 mm for 2 of 5 teeth.

The teeth requiring root canal treatment had the crack located on the distal marginal ridge in 15 of the 27 cases (56%). The distribution was mandibular second molars (6/27, 27%), mandibular first molars (3/27, 11%), maxillary first molars (3/27, 11%), maxillary second premolars (2/27, 7%), and maxillary second molars (1/27, 4%). The crack was located only on the mesial marginal ridge in 4 of the 27 cases (15%). The distribution was the maxillary first molars (3/27, 11%) and maxillary first premolars (1/27, 4%). Both marginal ridges were involved in 8 of the 27 cases (29%). The distribution was mandibular first molars (5/27, 19%), maxillary first molars (2/27, 7%), and maxillary second molars (1/27, 4%). None of the teeth had fractures that extended into the floor of the chamber or rendered them "non-restorable".

None of the original remaining 100 cases of RP required root canal treatment.

Discussion

The patients who composed this database were all patients referred to a private practice endodontist. Our incidence data are in agreement with the findings of Weine et al (5), which were also derived from an endodontist's practice. The difference in percentages from

How many pulps eventually died? 20%

other studies might be largely due to the nature of general dental populations versus an endodontic specialty population. Hiatt (5) and Cameron (4) reported maxillary premolars having the second highest incidence of cracks, which represents a periodontist and general dental practice. Therefore, this study's population might be under-represented with respect to premolars and the actual incidence of cracked teeth in the population at large.

This study found that 21% of the cases diagnosed with RP and a crack eventually required root canal treatment. Although no other studies have reported this finding, there have been studies examining the necessity for root canal treatment on teeth restored with crowns. Saunders and Saunders (7) reported that 19% of crowned teeth in a Scottish dental school population had root canal treatment after crown placement. This study was unable to report whether cracks were present before the crown was placed.

Cheung et al (8) found that 15% (19/122) of teeth restored with a ceramo-metallic crown required root canal treatment after crown placement in a population in Asia. They also found that of those serving as an abutment of a fixed-fixed bridge (25/77), 32% required root canal treatment after final cementation of the bridge.

Although the populations in these 2 studies are quite diverse, the similar percentages for teeth requiring root canal treatment after crown placement suggest that 15%–19% of their patients are to be expected for all crowns. The 21% of the cases in this study with RP and cracks that were crowned and subsequently required root canal treatment is only slightly higher than the 15%–19% and suggests similar incidence data.

When examining a tooth with both mesial and distal marginal ridge fractures, the natural assumption would be that more of these teeth would eventually require root canal treatment. Our data showed more teeth with a single marginal ridge crack, either mesial or distal, eventually required root canal treatment. This underlines the difficulty in predicting the eventual need for root canal treatment in teeth with RP and a cracked marginal ridge.

Conclusions

The outcomes of this study suggest that if a crack is identified early enough in cases with a diagnosis of RP and a crown is placed, root canal treatment will be necessary in about 20% of these cases within a 6-month period. Progression of interproximal periodontal defects associated with the crack(s) will occur in a very small percentage of the cases (5/127, 4%).

What is the pulpal death rate for any tooth w/ a crown? 15-19%

other studies might be largely due to the nature of general dental populations versus an endodontic specialty population. Hiatt (3) and Cameron (4) reported maxillary premolars having the second highest incidence of cracks, which represents a periodontist and general dental practice. Therefore, this study's population might be under-represented with respect to premolars and the actual incidence of cracked teeth in the population at large.

This study found that 21% of the cases diagnosed with RP and a crack eventually required root canal treatment. Although no other studies have reported this finding, there have been studies examining the necessity for root canal treatment on teeth restored with crowns. Saunders and Saunders (7) reported that 19% of crowned teeth in a Scottish dental school population had root canal treatment after crown placement. This study was unable to report whether cracks were present before the crown was placed.

Cheung et al (8) found that 15% (19/122) of teeth restored with a cerano-metallic crown required root canal treatment after crown placement in a population in Asia. They also found that of those serving as an abutment of a fixed-fixed bridge (15/77), 32% required root canal treatment after final cementation of the bridge.

Although the populations in these 2 studies are quite diverse, the similar percentages for teeth requiring root canal treatment after crown placement suggest that 15%–19% of these patients are to be expected for all crowns. The 21% of the cases in this study with RP and cracks that were crowned and subsequently required root canal treatment is only slightly higher than the 15%–19% and suggests similar incidence data.

When examining a tooth with both mesial and distal marginal ridge fractures, the natural assumption would be that more of these teeth would eventually require root canal treatment. Our data showed more teeth with a single marginal ridge crack, either mesial or distal, eventually required root canal treatment. This underlines the difficulty in predicting the eventual need for root canal treatment in teeth with RP and a cracked marginal ridge.

Conclusions

The outcomes of this study suggest that if a crack is identified early enough in cases with a diagnosis of RP and a crown is placed, root canal treatment will be necessary in about 20% of these cases within a 6-month period. Progression of interproximal periodontal defects associated with the crack(s) will occur in a very small percentage of the cases (5/127, 4%).

Is monolithic injection molded composite a viable alternative to full ceramic crowns in some cases?

You be the judge of that

The patient is a 35- year-old male. His original chief complaint was a discolored filling on the distal of tooth #8. The patient was given two treatment plans, one to simply replace a few defective restorations and remove caries with traditional fillings or in patient terms we said, “We can patch the holes, or I can rejuvenate your smile. The patchwork plan will be healthy but will not make a significant esthetic change. In addition, the severe wear and acid erosion present on the palatal surfaces could eventually lead to catastrophic problems later i.e. root canals, infection, and tooth loss.” The patient opted for Bioclear rejuvenation versus simple fillings because he wanted a beautiful smile. He chose Bioclear in lieu of crowns because he understood that Bioclear is a more conservative and healthier approach to achieving his goals than traditional crowns.

Phase one of the treatment plan was to restore the anterior six teeth, simultaneously opening the vertical dimension to reduce the need for aggressive tooth reduction for material thickness. In addition, because the patient needed to have the teeth lengthened by 2 mm, opening the vertical dimension by 2 mm allowed the overbite to be more ideal. Because the patient could only commit to the cost of the six Bioclear restorations ($11,600) we placed transitional occlusal flowable composites (thick sealants) on the four maxillary premolar teeth, and we will allow the molars to settle into occlusion utilizing the well-researched Dahl Technique.

Phase two will be to restore the remaining teeth with Bioclear when the patient has his finances ready.

Treatment Summary Short Version:

Treatment was finished in a single 4-hour session. (Less experienced clinicians should plan to give one hour per tooth). Bioclear TSS Matrices were utilized on all the teeth except tooth #10. #10 required the Bioclear BT matrix system to create “instant ortho” and because a diastema was present there. Bioclear Diamond wedges were used as needed in areas where the contact was lost during caries removal or removal of old composites. Bioclear RSP X-course discs (Black) were used to shape the incisal edges and smooth the small seams present where the matrices meet on the facial and palatal. Final polish was achieved with Bioclear Magic Mix and then Rock Star Polish cups and cones.

One-week postoperative visit revealed healthy teeth and gingiva. The patient was ecstatic about his new smile, had zero post-operative pain or sensitivity, and expressed that his new bite with the increase in VDO felt more comfortable than before.

...nitive Diagnosis of Early Enamel and Dentinal ...cks Based on Microscopic Evaluation

DAVID J. CLARK, DDS*
CHERILYN G. SHEETS, DDS†
JACINTHE M. PAQUETTE, DDS‡

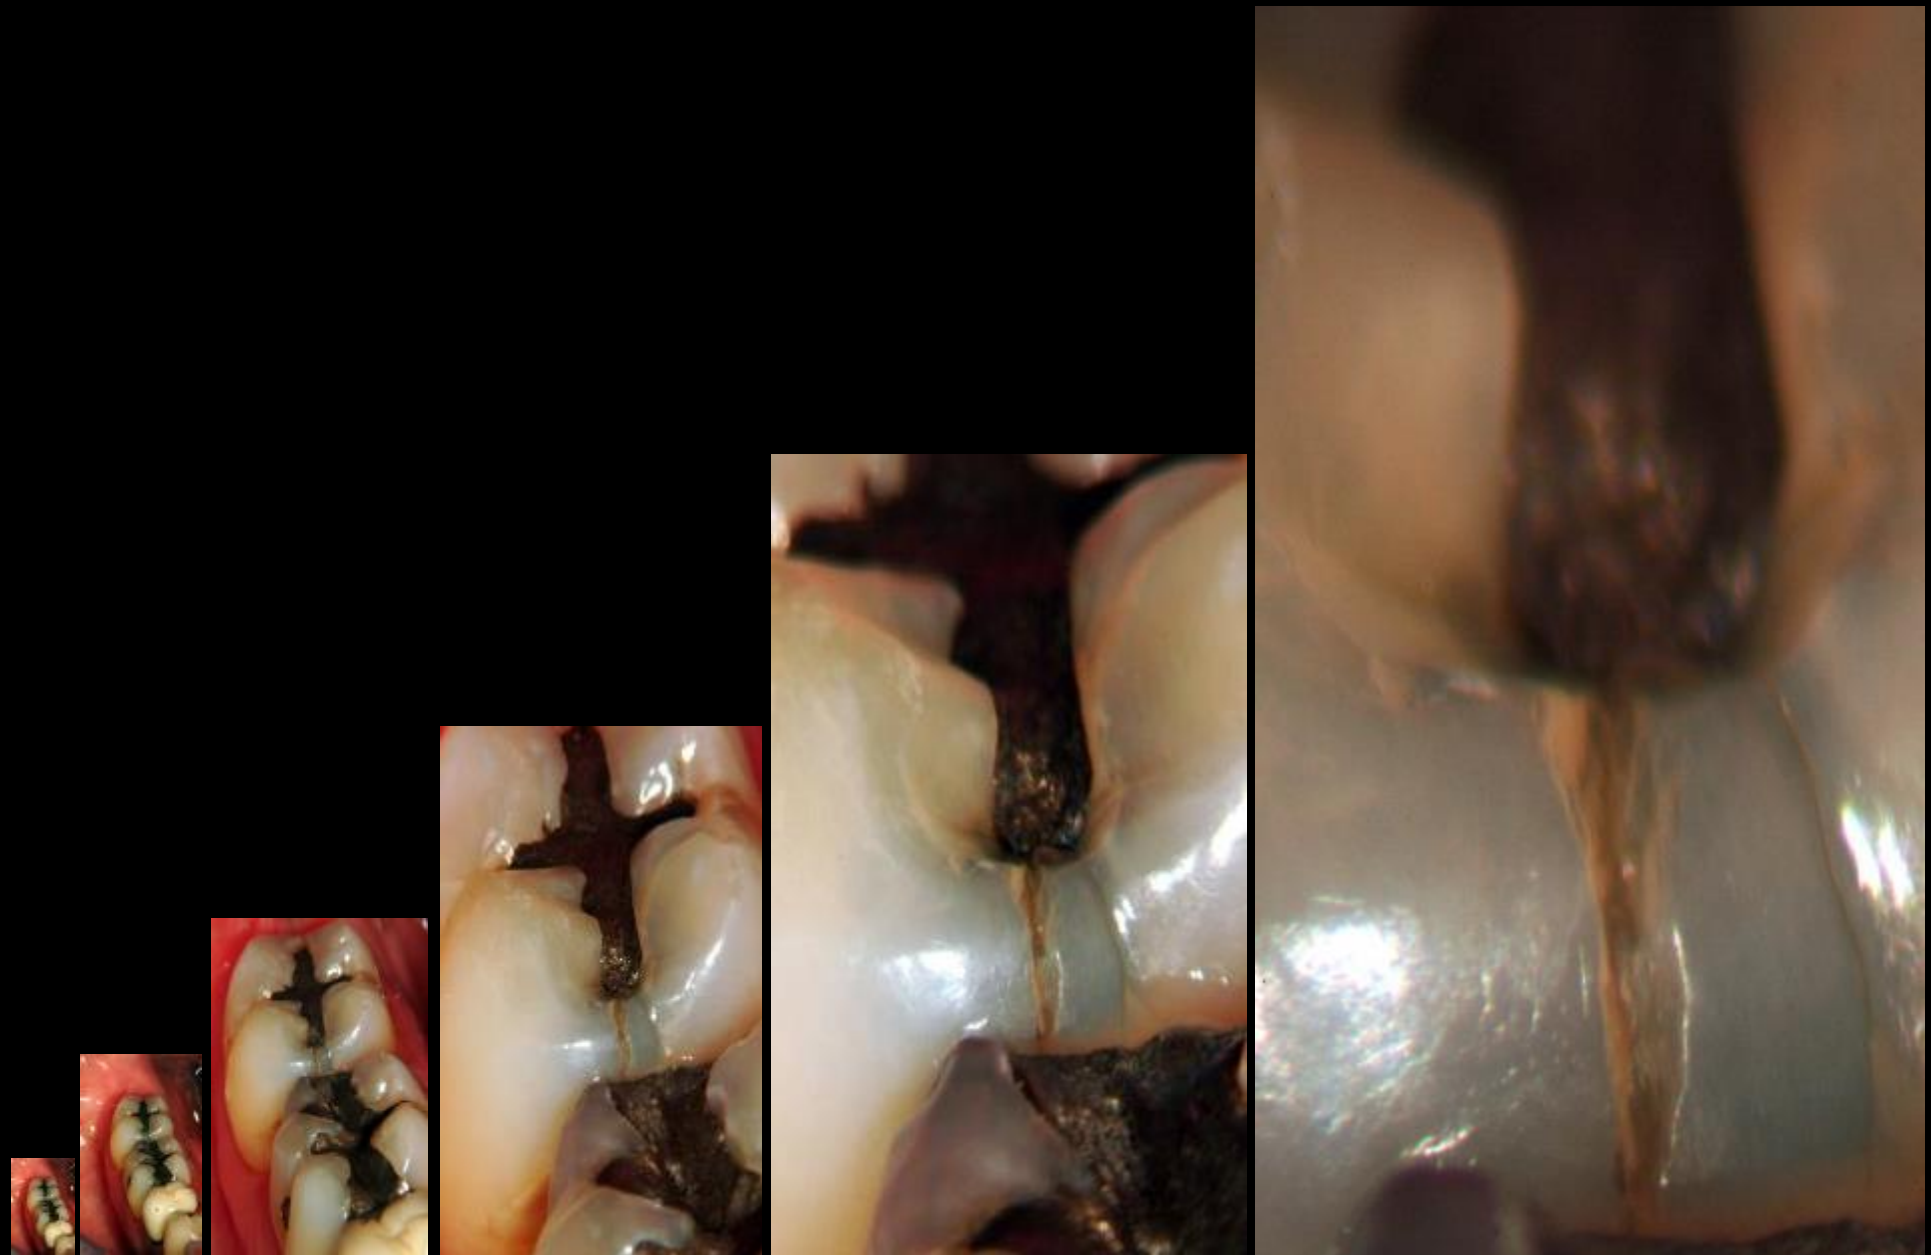
CLINICAL SIGNIFICANCE

This article gives new guidelines for recognition, visualization, classification, and treatment of cracked teeth based on the routine use of ×16 magnification. The significance of enamel cracks as they relate to dentinal cracks is detailed.

(J Esthet Restor Dent 15:XXX–XXX, 2003)

Microscopic and symptom-driven diagnoses have been the accepted modalities for cracked teeth. The inherent limitations of the lack of visual confirmation result in therapies that often come too late in the treatment process. One lasting first impression of vision through a clinical microscope is the staggering array of cracks that exist within tooth structures. Traditional visualization (unaided or ocular assisted) limits the clinician's ability to assess the presence or severity of the majority of these cracks (Figure 1).

At extreme magnification levels (×14 and greater), the translucent nature of enamel yields a wealth of information. Subtle color changes within the enamel may indicate early decay, microleakage, and a lack of structural integrity of dentin and enamel. Being able to see previously invisible clues can lead restorative dentists to more appropriate early treatment of compromised teeth before devastating fractures, pulpal involvement, and periodontal breakdown occur. The value of early diagnosis of the structural breakdown of teeth will become even more significant with our aging population coupled with increased tooth retention in this population.



One of the enduring first impressions of clinical microscope dentistry is the staggering array of cracks that are suddenly visible

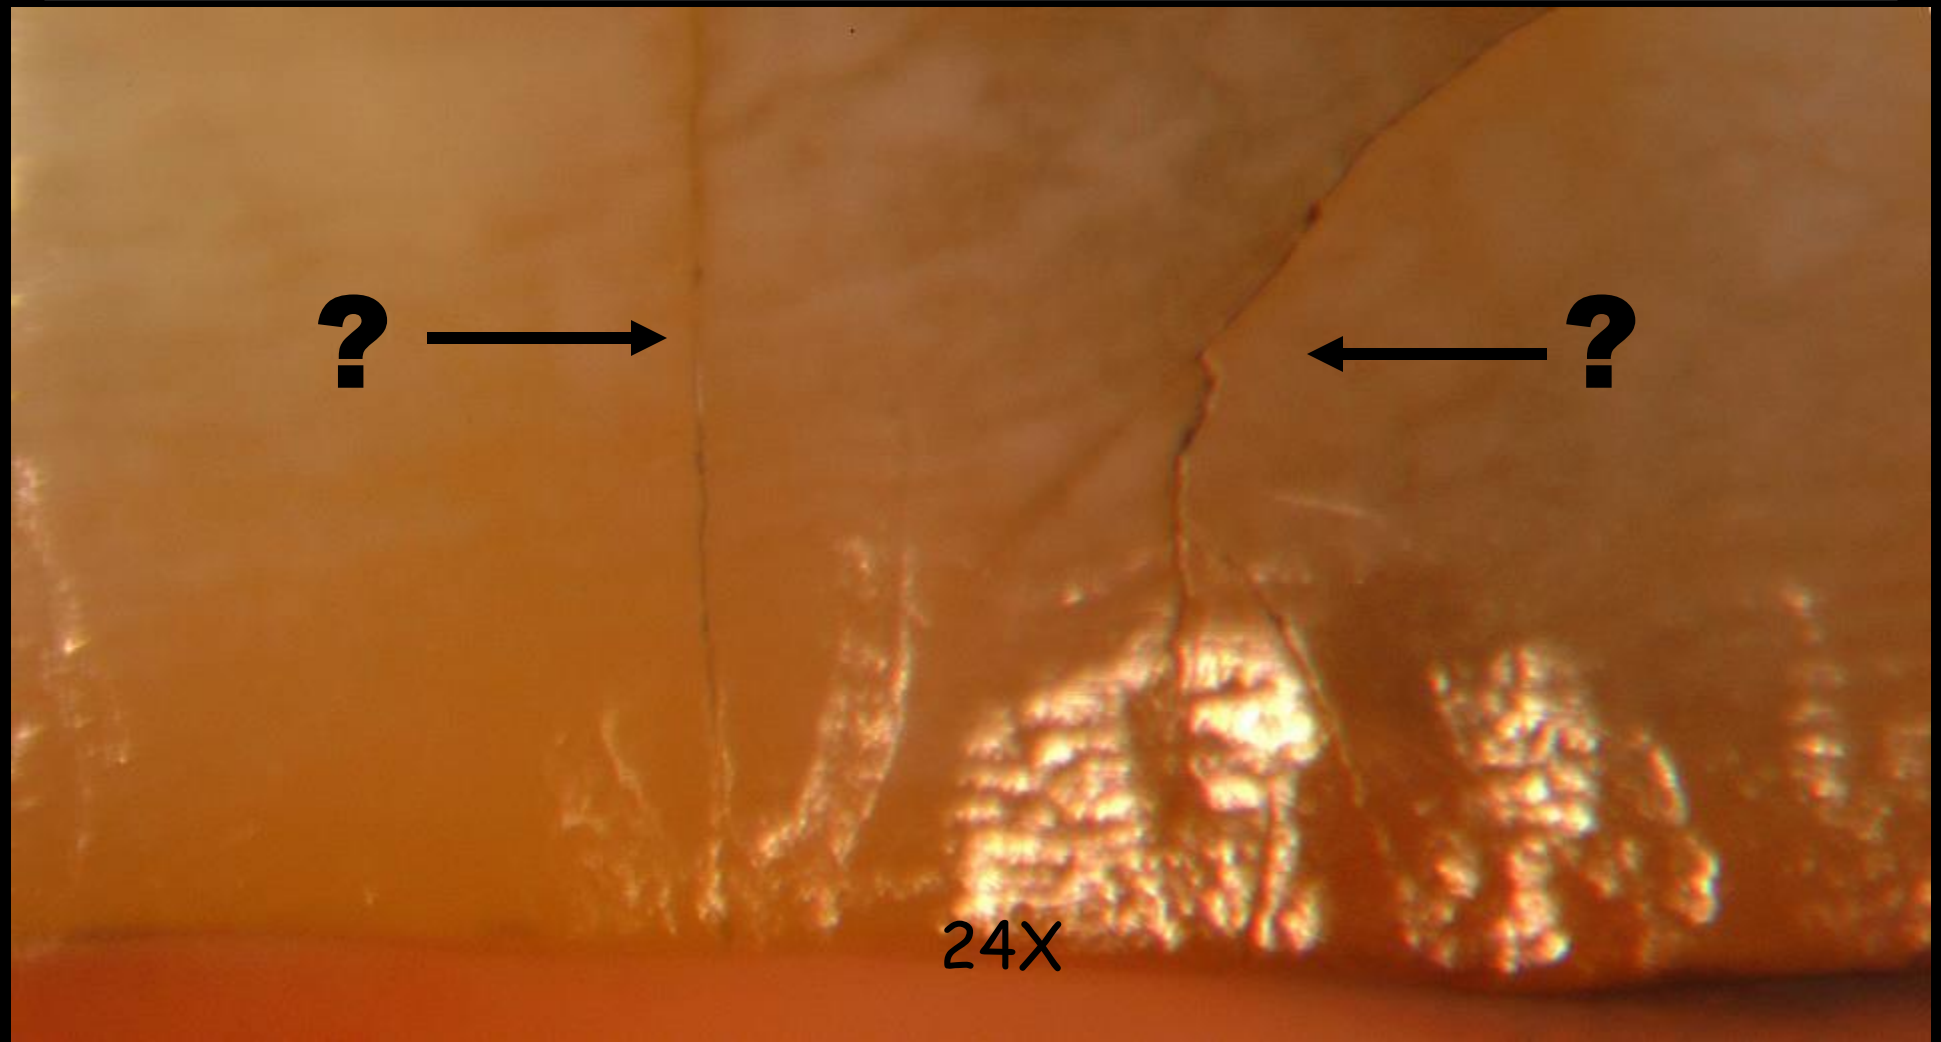
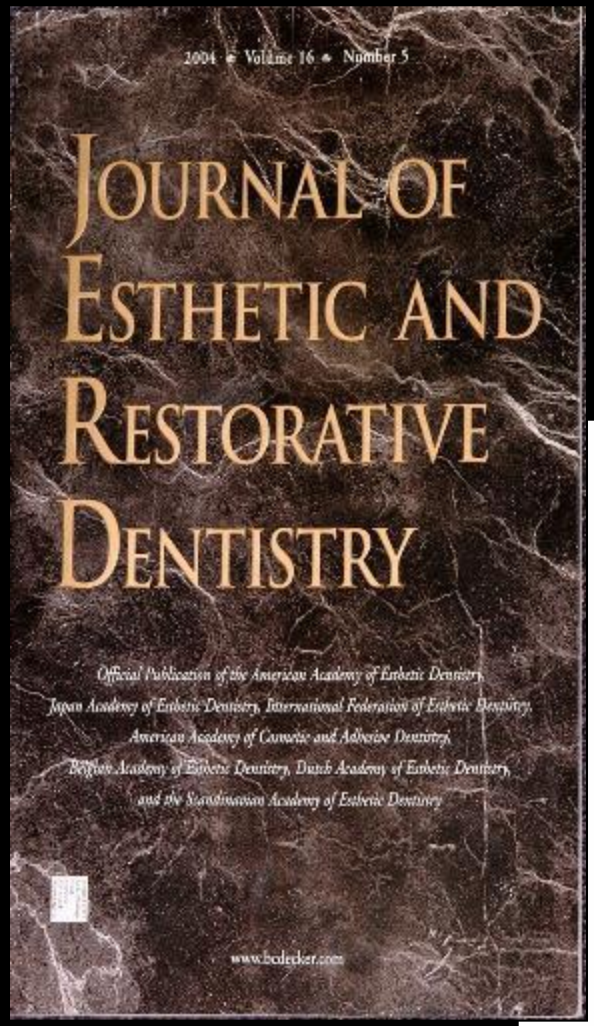
Which enamel crack is "native", which crack is indicative of underlying pathology?





Definitive Diagnosis of Early Enamel and Dentinal Cracks Based on Microscopic Evaluation

BRUCE J. GLASS, DDS*
CHERILYN G. SHEETS, DDS†
JACQUES M. RAQUET, DDS‡

ABSTRACT

The diagnosis of cracked teeth and incomplete coronal fracture have historically been symptom-based. The detailed operating microscope at 16 magnification can fundamentally change a clinician's ability to diagnose such conditions.

Clinicians have been observing cracks under extreme magnification for nearly a decade. Patterns have become clear that can lead to appropriate treatment prior to symptoms or devastation to tooth or tissues occurs. Conversely, many cracks are not structural and can lead to misdiagnosis and overtreatment. Methodic microscopic examination, an understanding of crack progression, and an appreciation of the types of cracks will guide a doctor to making appropriate decisions.

Teeth can have structural cracks in various stages. To date, diagnosis and treatment are very often at end stage of crack development.

CLINICAL SIGNIFICANCE

This article gives new guidelines for recognition, examination, classification, and treatment of cracked teeth based on the routine use of 16 magnification. The significance of enamel cracks as they relate to coronal cracks is detailed.

(J Esthet Restor Dent 15:XXX–XXX, 2003)

Microscopic and symptom-driven diagnoses have been the accepted modalities for cracked teeth. The inherent limitations of the lack of visual confirmation result in therapies that often come too late in the treatment process. One limiting factor: impressions of vision through a dental microscope is the staggering array of cracks that exist within tooth structures. Traditional visualization (unaided ocular assisted) limits the clinician's ability to assess the presence or severity of the majority of these cracks (Figure 1).

At extreme magnification levels (16 X magnification), the translucent nature of enamel yields a wealth of information. Subtle color changes within the enamel may indicate early decay, microleakage, and a lack of structural integrity of dentin and enamel. Being able to see previously invisible clues can lead restorative dentists to more appropriate early treatment of compromised teeth before devastating fractures, pulpal involvement, and periodontal breakdown occur. The value of early diagnosis of the structural breakdown of teeth will become even more significant with our aging population complex with increases in tooth retention in this population.

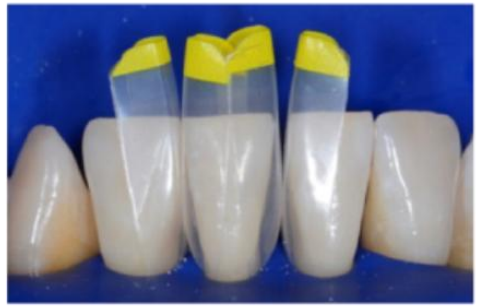
Getting paid to be conservative

BIOCLEAR VS. CROWNS AND VENEERS

Bioclear is an alternative to traditio
for enhancing a smile. Rather than
to prepare for a crown or veneer, th
ensconcing the natural tooth struct
tooth enamel and tooth durability.



BIOCLEAR PREPARATION
Bioclear allows dentists to **conserve** healthy tooth structure

CROWN PREPARATION
Crowns require dentists to **remove an average of 76%** of the tooth structure prior to the procedure

VENEER PREPARATION
Veneers require dentists to **remove an average of 47%** of the tooth structure prior to the procedure

AN HONEST LOOK AT CROWN PREPARATIONS

As illustrated below, crowns, veneers, and onlays require the removal of a significant amount of healthy tooth structure. Bioclear dentists can leave most or all of the tooth structure. Bioclear is a very attractive option to patients.

~3/4 Crown
47% of tooth removed

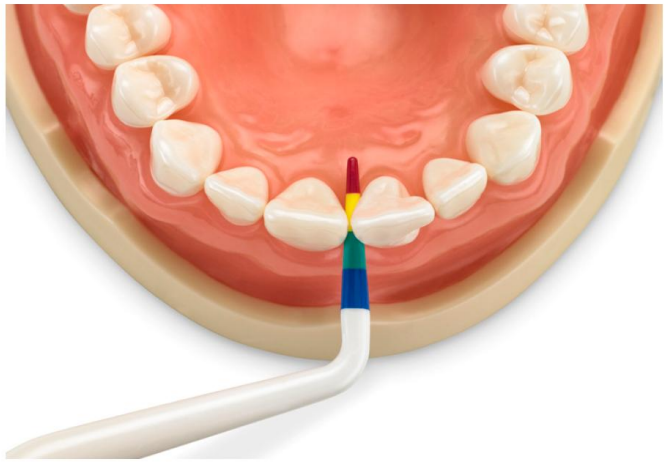
BLACK TRIANGLE

CERTIFICATION COURSE

18 CE CREDITS

This three-part live hands-on certification course will teach you how to treat black triangles, gingival recession, root abrasions, and perform confident restorations. In becoming a certified Bioclear black triangle doctor, you'll increase your overall skill and knowledge of Bioclear and learn to market your new skills to patients.



Upcoming Dates:

Denver
October 9th 2026

Walnut Creek
August 21st 2026

Limited spots available!

OUR MISSION

BIOCLEAR LEARNING CENTER

The Bioclear Learning Center aims to improve restorative outcomes and raise patient expectations of modern composite dental care by providing dentists with continuing education and certification in the practice of the Bioclear Method.

- The Learning Center is equipped with exclusive, patented Bioclear tools, equipment, and your own operatory setup
- Small class sizes with hands-on, interactive curriculum modules
- Online class options available at the convenience of your practice
- Operate a Tell, Show, Do education model
- Learn and understand the Five Pillars of the Bioclear Method

BIOCLEAR

4-DAY CORE ANTERIOR & POSTERIOR COURSE

36 CE CREDITS

This course builds a strong foundation in the Bioclear Method and an understanding of Bioclear products. The focus of the course is indirect methods on adult dentitions as an alternative procedure to porcelain crowns and veneers.

Students will learn the foundation of posterior and anterior restorations and are introduced to the engineering principles involved in the design of the new non-retentive compression-based preps. Students collaboratively practice all applications of the Bioclear Method during intensive, hands-on exercises that simulate posterior and anterior restorations.

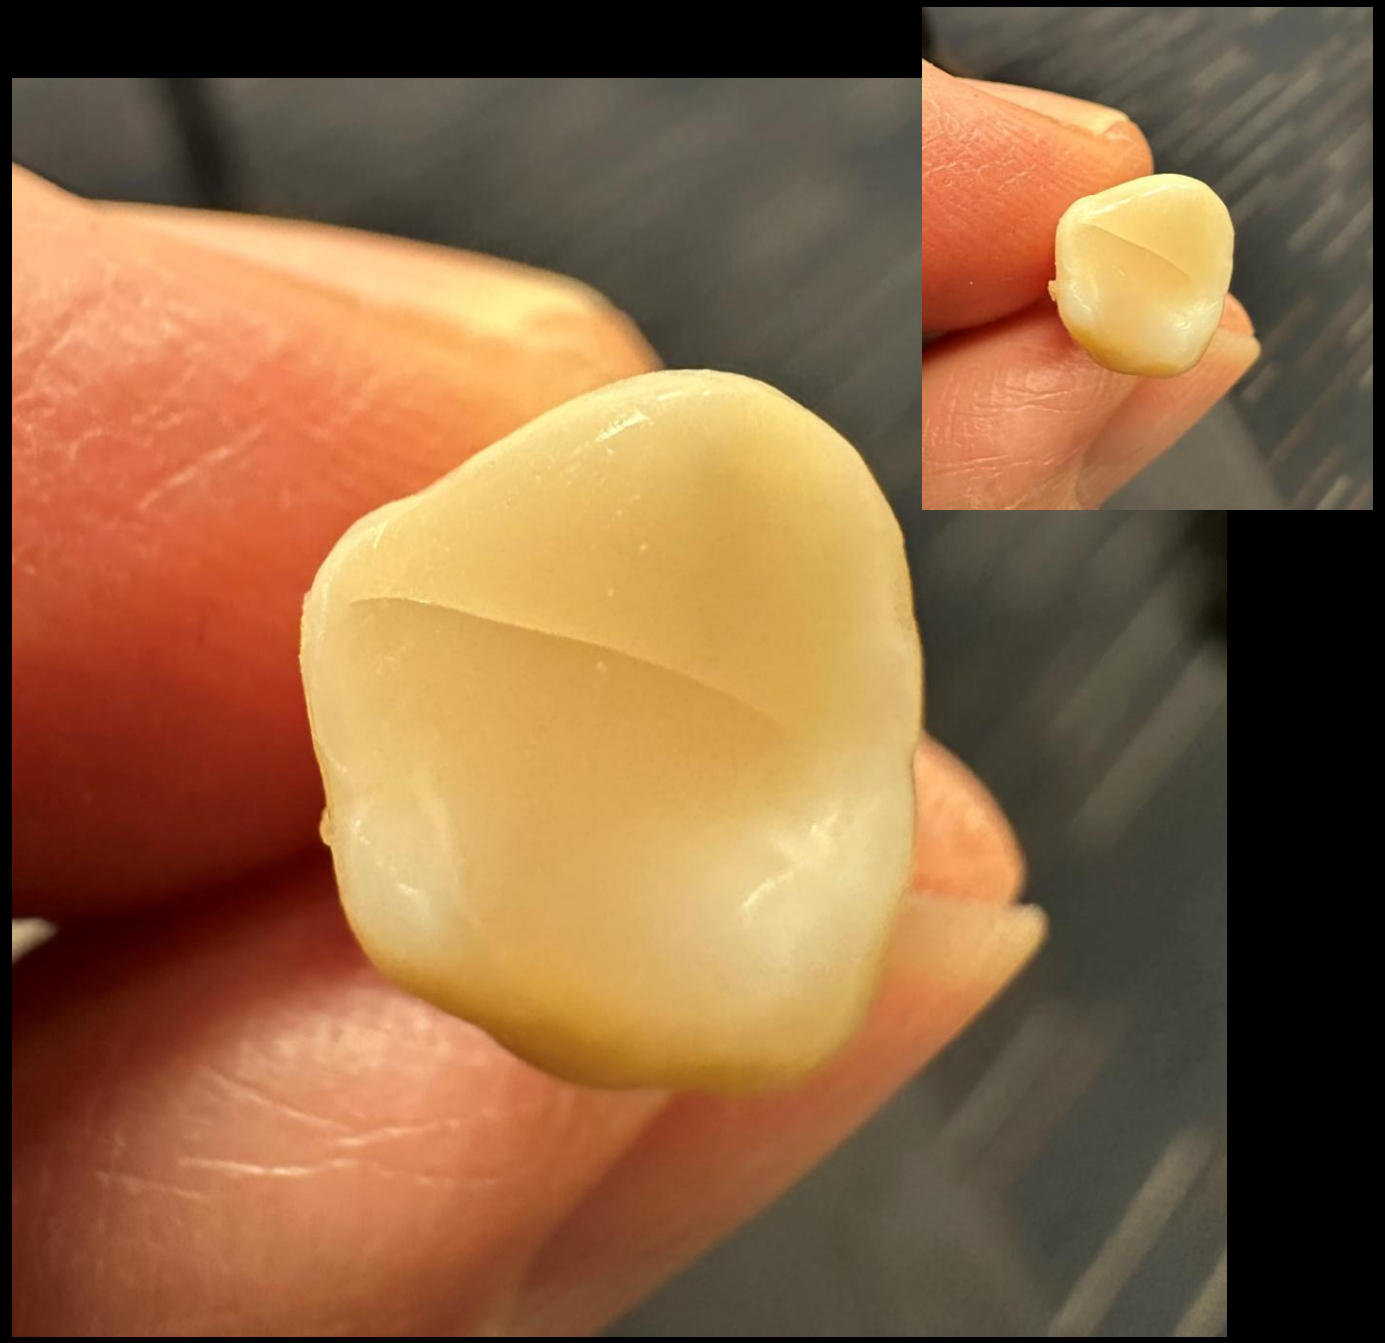
Miles ahead of everybody else for Bulk Fills

YIKES!!
GC “Bulk Injectable”

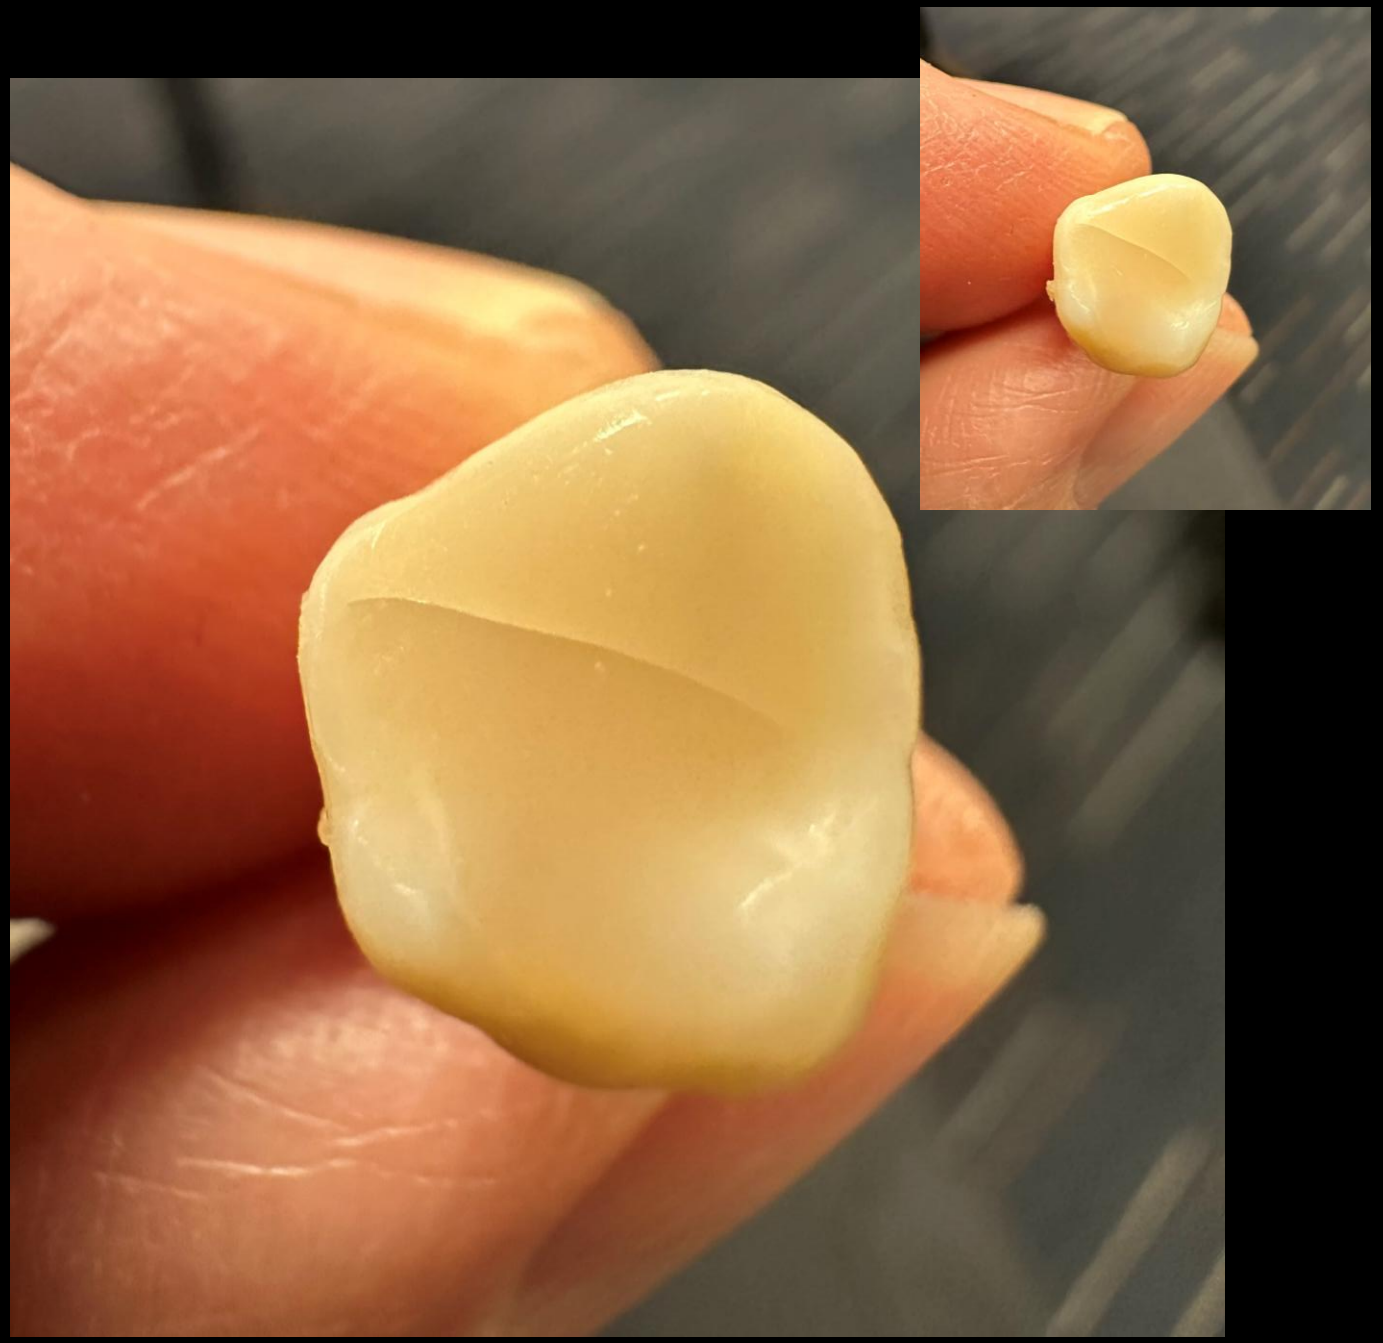
Discussion:

Polymerization shrinkage stress and cuspal deflection is very real but challenging to explain



Discussion:

The volume of composite, and residual strength of the tooth are key players. If half of tooth is missing, ie there is a good sized hole in the occlusal or interproximal, we are recommending Filtek One (bulk fill paste) plus GC bulk flow or Filtek bulk flow.



Discussion:

If you we have a fair amount of dentin removed, we need Filtek One

Miles ahead of everybody else for Bulk Fills

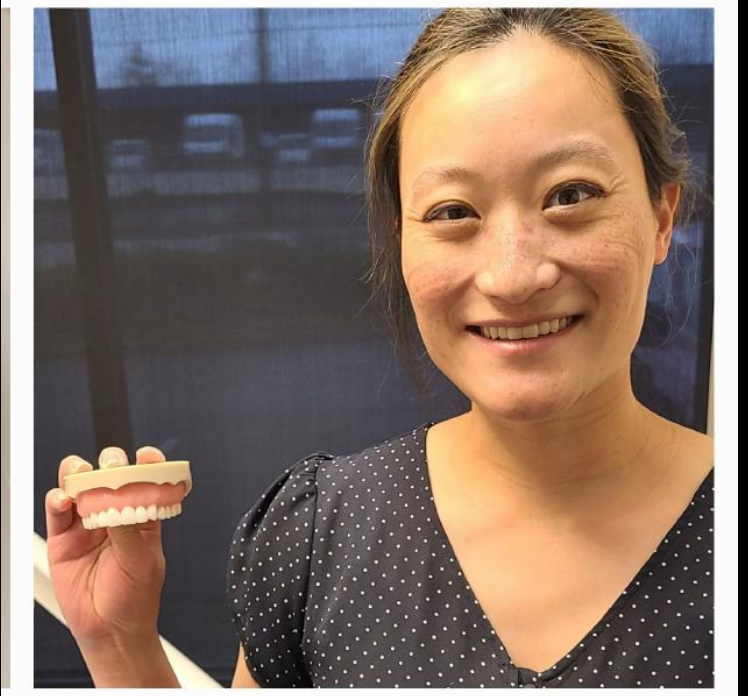
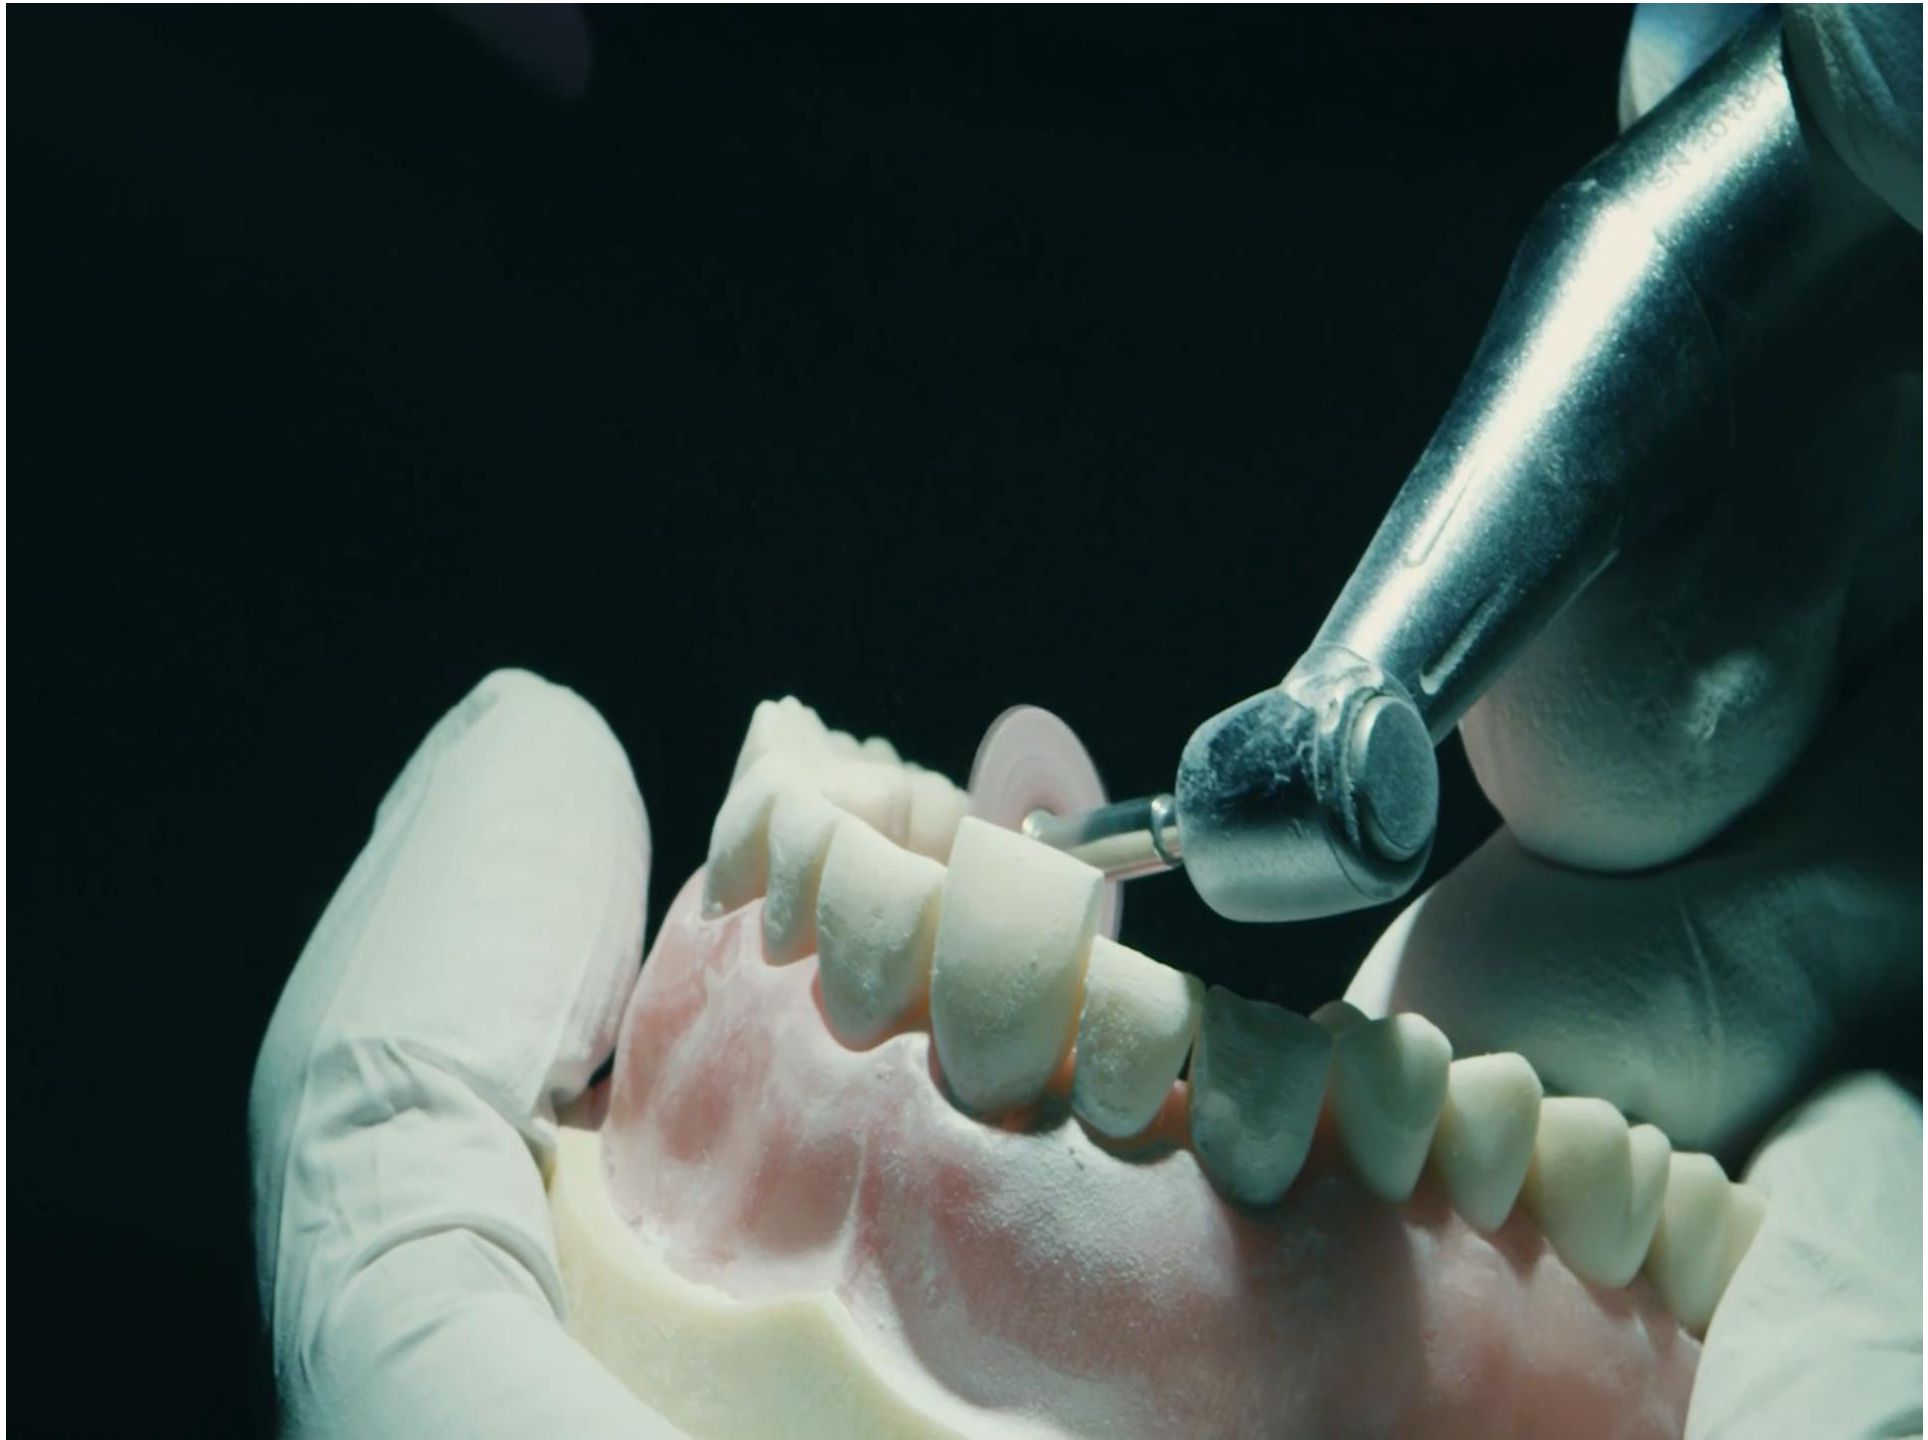
Bioclear Method for Composite Restorations



Last week’s attendees at the certification course



Hands-On Workshop: Better, Faster, Prettier Composite Dentistry - 3 CE 1:45PM-4:15PM

- Audience: Hands-On Workshop Pre-registered $100
- Location: Room 410 C, Boise Centre East
- **by Dr. David Clark, Bioclear**

Experience a fresh approach to modern composite dentistry with Dr. Clark. Say goodbye to traditional techniques like
layering, condensing, and burnishing. Join us to master injection molding, achieving precise margins, smooth
contours, and flawless, mirror-like restorations in both black triangle and Class II scenarios.

- Learn: The 6 steps to achieve rock solid posterior contacts in even the most difficult cases
- Learn: How can you combine flowable & regular composites with the injection molding technique & when to use bulk fills
- Learn: Treating the dreaded black triangle, especially common after tray aligner therapy
- Learn: How to handle heated composites

solventum
(3M)

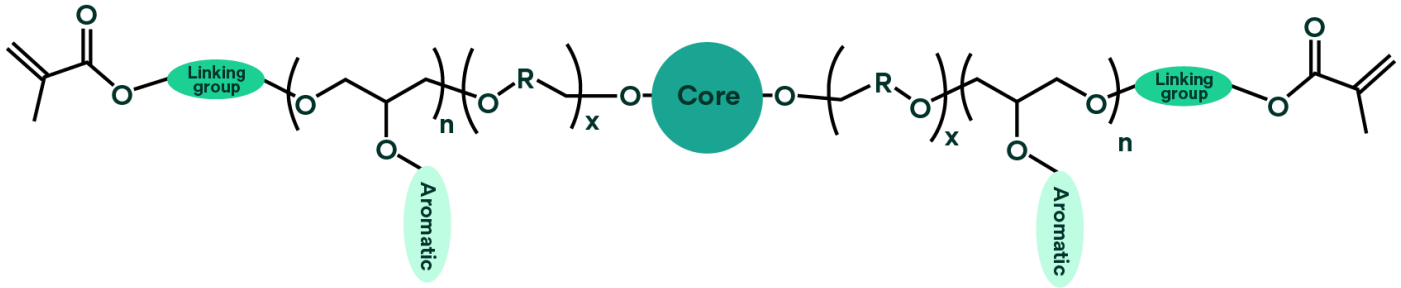
3M™ Filtek™ One Bulk Fill Restorative

Scientific presentation

Innovative methacrylate monomers for lower shrinkage and proven stress relief

AUDMA: Aromatic urethane dimethacrylate

- Higher molecular weight with less number of reactive groups
- Moderates volumetric shrinkage
- Contributes to stress reduction



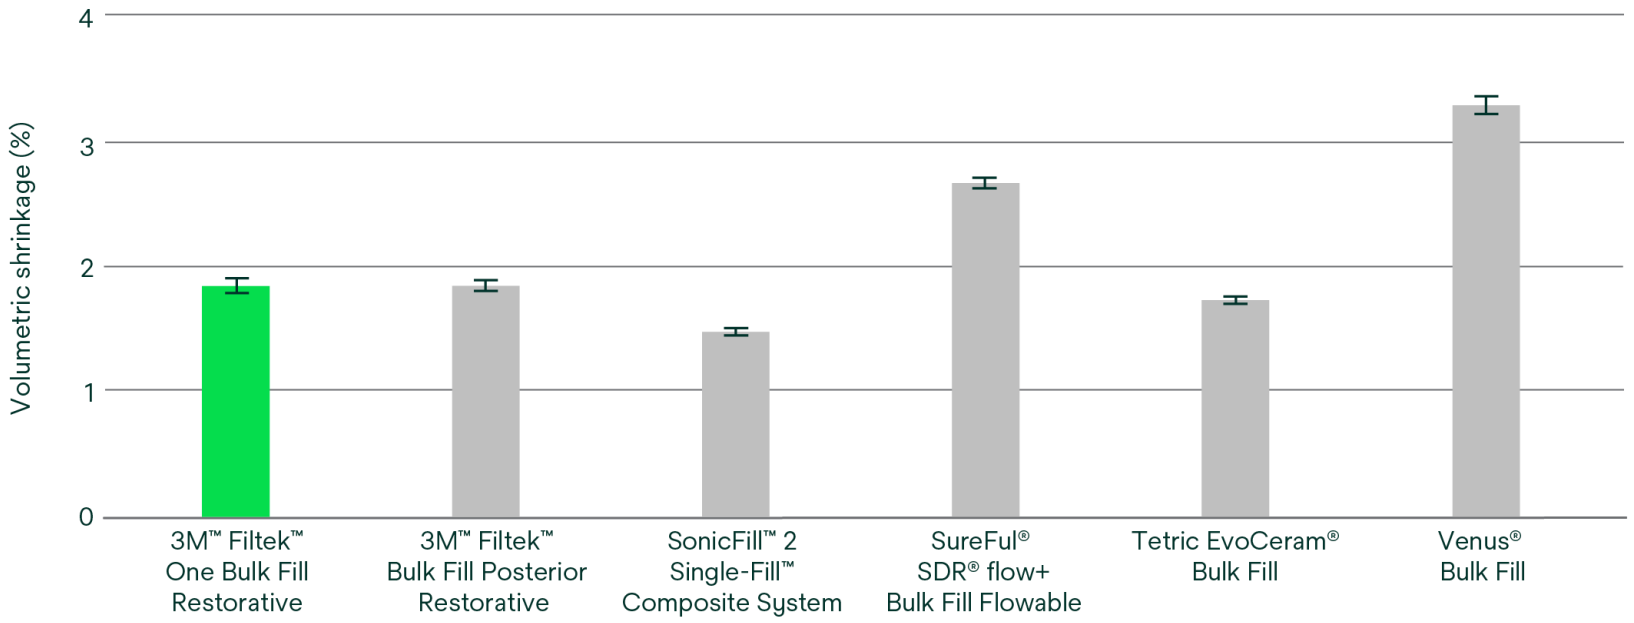
AFM: Addition-fragmentation (AF) monomer

- Reacts into developing polymer network through terminal methacrylate bonds like other dimethacrylate monomers
- Central AF group can fragment and release stress
- Fragment may then polymerize into network in a lower stress orientation compared to its pre-fragmented state

solventum

Polymerization shrinkage

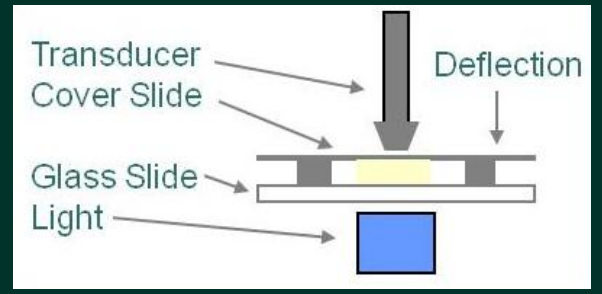
Comparison of common bulk fill composites



Source: Solventum Internal Data

3M™ Filtek™ One Bulk Fill Restorative

is equivalent to 3M™ Filtek™ Bulk Fill Posterior and has lower polymerization shrinkage than Venus® Bulk Fill, Surefil® SDR® Flow +.

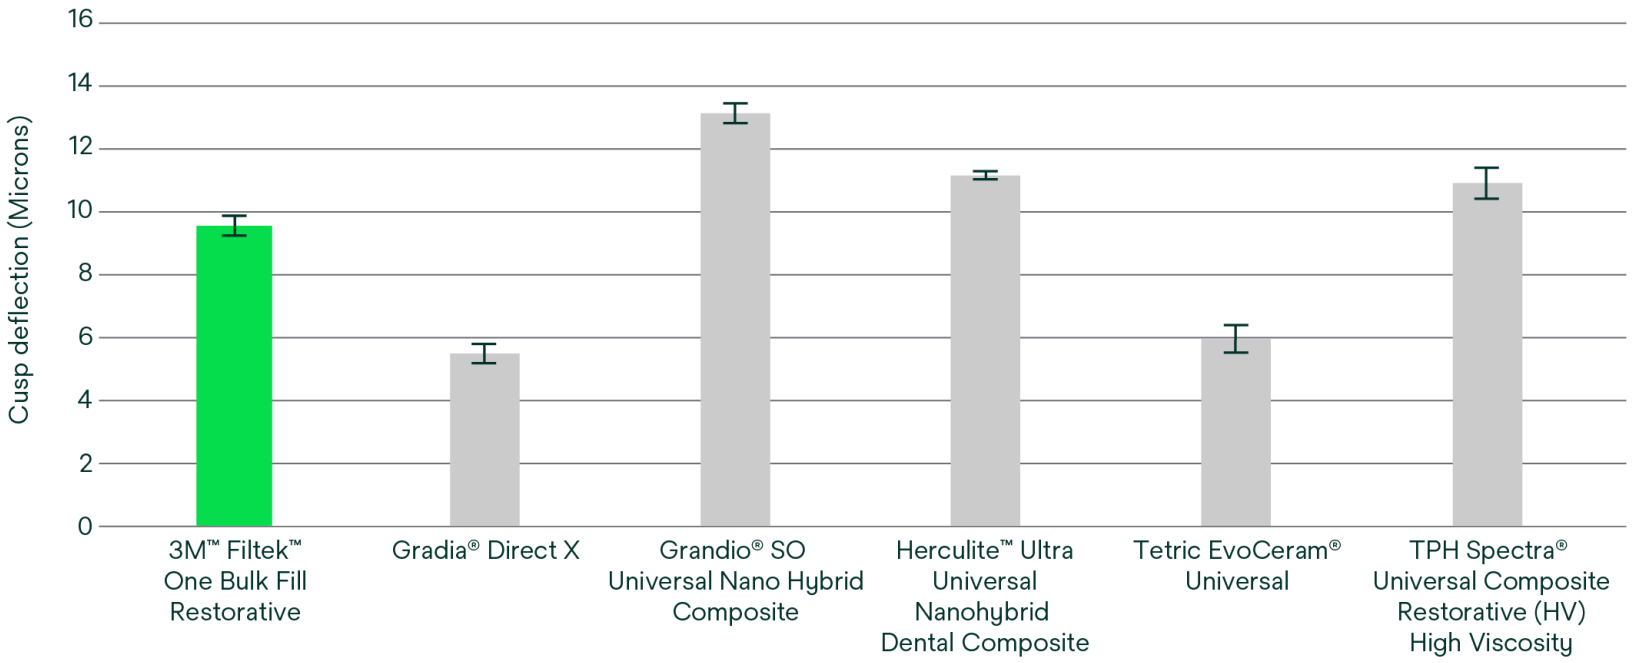


Bonded disc method

solventum

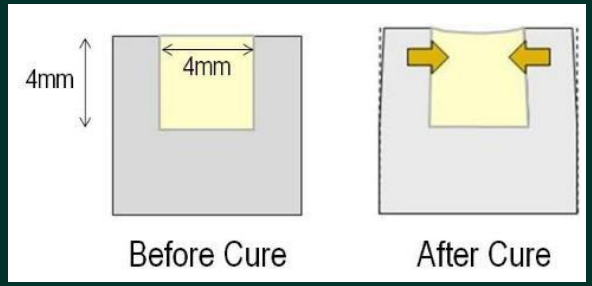
Polymerization stress

Comparison of common universal composites



Source: Solventum Internal Data

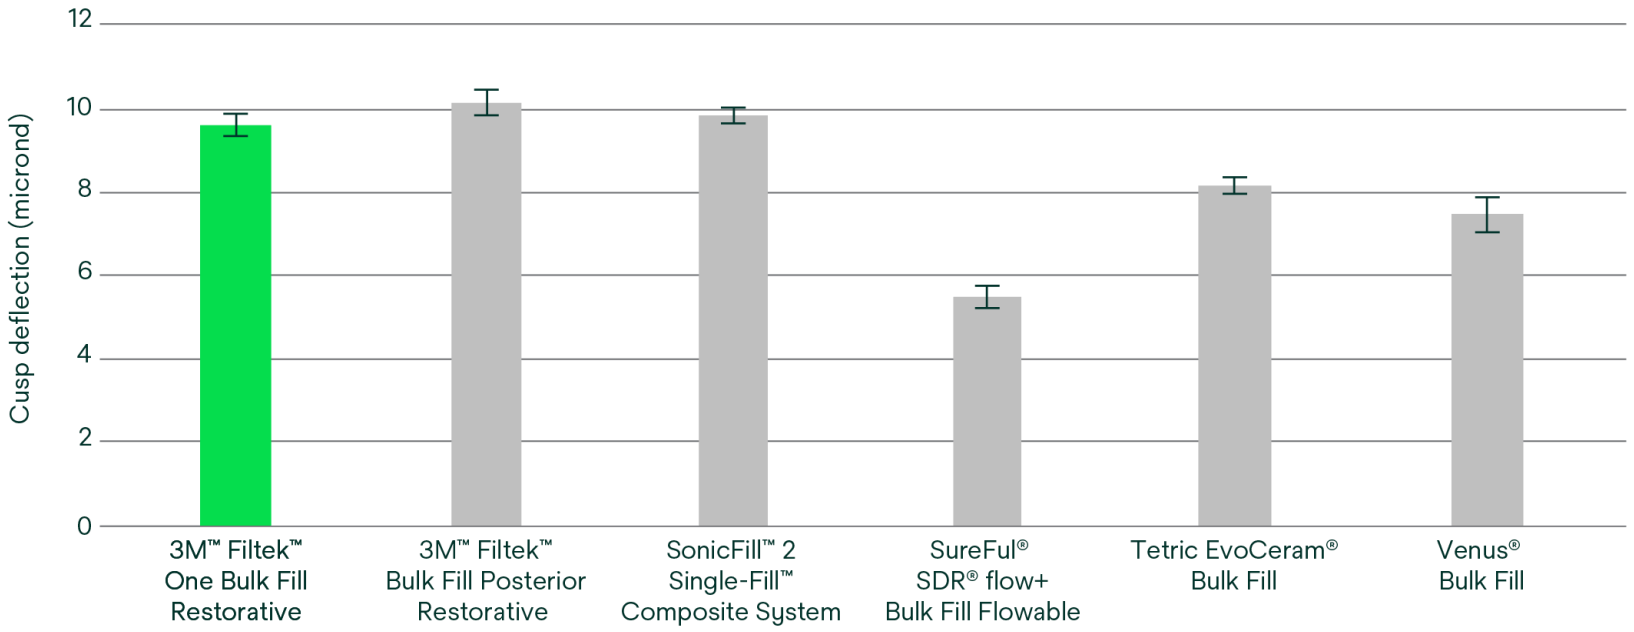
3M™ Filtek™ One Bulk Fill Restorative has similar polymerization stress when placed in bulk compared to many of the universal materials that are placed in increments.



solventum

Polymerization stress

Comparison of common bulk fill composites



Source: Solventum Internal Data

3M™ Filtek™ One Bulk Fill Restorative has similar polymerization stress compared to 3M™ Filtek™ Bulk Fill Posterior Restorative and SonicFill™ 2.
